# Prologue

## Why do we care about hadron spectroscopy?

- Because it allows us to understand **how the QCD degrees of freedom manifest in nature**. The role of models is crucial
- Because we need a better understanding of hadron amplitudes if we want to **reduce the «hadronic uncertainties»** in precision physics (e.g.  $\tau$  EDM,  $g_\mu - 2$ , CPV in hadronic  $B$  decays...)
- (the honest answer would be «**because we are nerds and we like it**», but we cannot reply like this to funding agencies)

# Outline

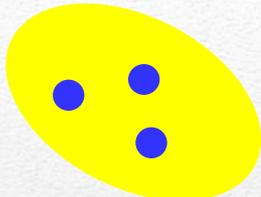

- The exotic landscape
- Amplitude analysis
  - The  $S$ -matrix principles
  - Case study for the  $Z_c(3900)$
  - The  $\eta\pi$  system
  - Three-body unitarity
  - The  $Y$  states
- Modeling
  - Diquark-antidiquark & Molecules
  - Production at colliders

# Hadron Spectroscopy

$\rho(770)$   $I^G(J^{PC}) = 1^+(1^{--})$   
 Review: The  $\rho(770)$

## $\rho(770)$ MASS

NEUTRAL ONLY, $e^+e^-$	$775.26 \pm 0.25$ MeV
CHARGED ONLY, $\tau$ DECAYS and $e^+e^-$	$775.11 \pm 0.34$ MeV
MIXED CHARGES, OTHER REACTIONS	$763.0 \pm 1.2$ MeV

### Mass $m$

CHARGED ONLY, HADROPRODUCED	$766.5 \pm 1.1$ MeV
NEUTRAL ONLY, PHOTOPRODUCED	$769.0 \pm 1.0$ MeV
NEUTRAL ONLY, OTHER REACTIONS	$769.0 \pm 0.9$ MeV (S = 1.4)
$m_{\rho(770)^0} - m_{\rho(770)^\pm}$	$-0.7 \pm 0.8$ MeV (S = 1.5)
$m_{\rho(770)^+} - m_{\rho(770)^-}$	
$\rho(770)$ RANGE PARAMETER	$5.3^{+0.9}_{-0.7}$ GeV <sup>-1</sup>

## $\rho(770)$ WIDTH

NEUTRAL ONLY, $e^+e^-$	$147.8 \pm 0.9$ MeV (S = 2.0)
CHARGED ONLY, $\tau$ DECAYS and $e^+e^-$	$149.1 \pm 0.8$ MeV
MIXED CHARGES, OTHER REACTIONS	$149.5 \pm 1.3$ MeV
CHARGED ONLY, HADROPRODUCED	$150.2 \pm 2.4$ MeV
NEUTRAL ONLY, PHOTOPRODUCED	$151.7 \pm 2.6$ MeV
NEUTRAL ONLY, OTHER REACTIONS	$150.9 \pm 1.7$ MeV (S = 1.1)
$\Gamma_{\rho(770)^0} - \Gamma_{\rho(770)^\pm}$	$0.3 \pm 1.3$ (S = 1.4)
$\Gamma_{\rho(770)^+} - \Gamma_{\rho(770)^-}$	$1.8 \pm 2.1$

## Potential models

(meaningful when  $M_Q \rightarrow \infty$ )

$$V(r) = -\frac{C_F \alpha_s}{r} + \sigma r$$

(Cornell potential)

Solve NR Schrödinger eq.  $\rightarrow$  spectrum

## Effective theories

(HQET, NRQCD, pNRQCD...)

Integrate out heavy DOF

(spectrum), decay & production rates

$$\alpha_s(M_Q) \sim 0.3$$

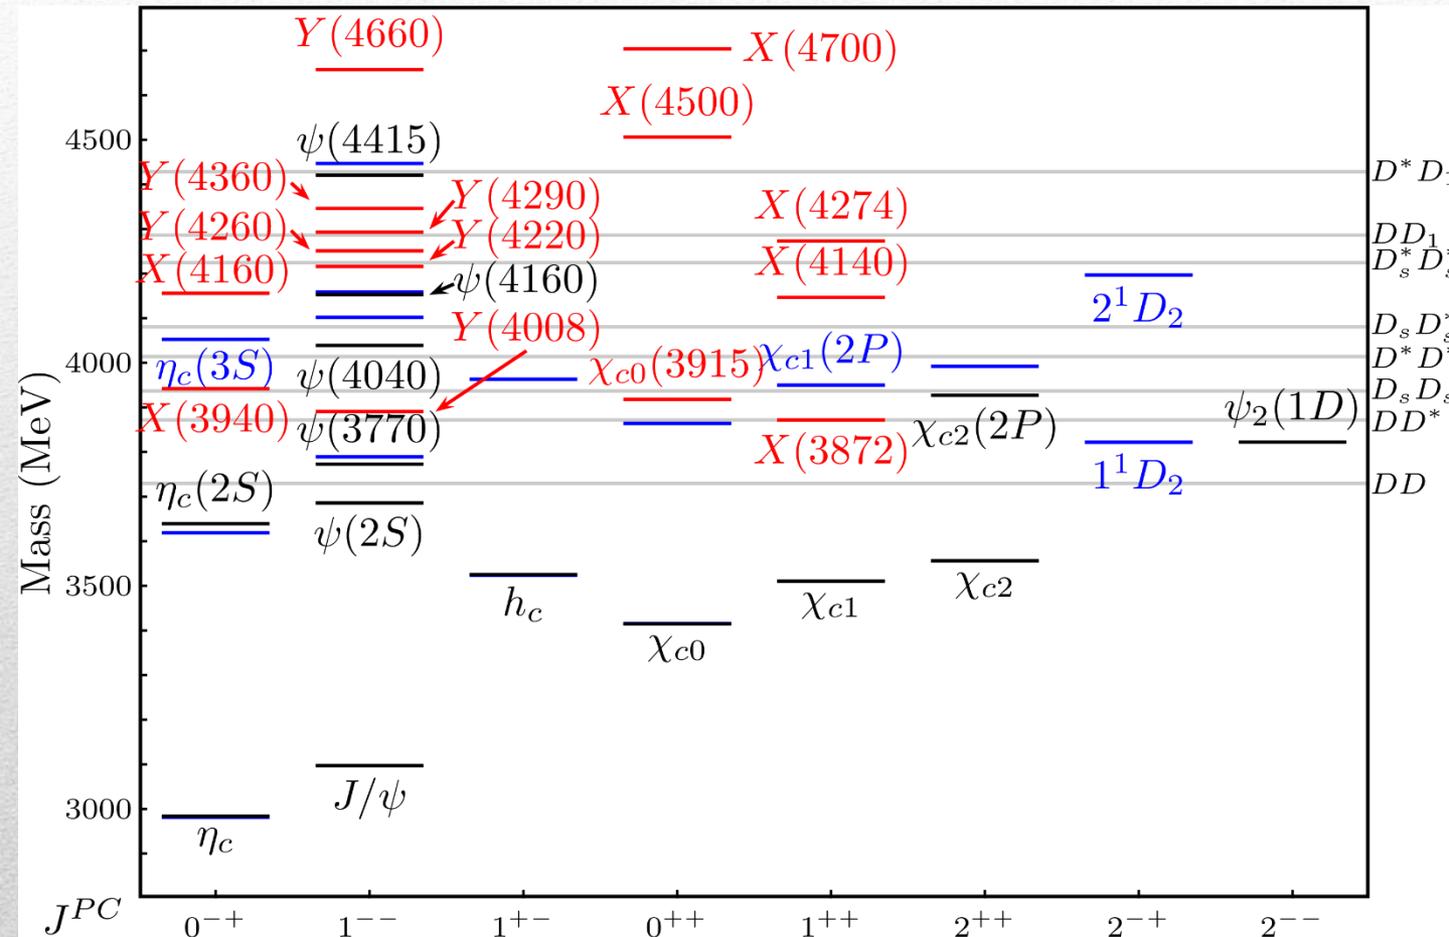

(perturbative regime)

OZI-rule, QCD multipole

Heavy quark spin flip suppressed by quark mass, approximate heavy quark spin symmetry (HQSS)

# Exotic landscape

Esposito, AP, Polosa, Phys.Rept. 668

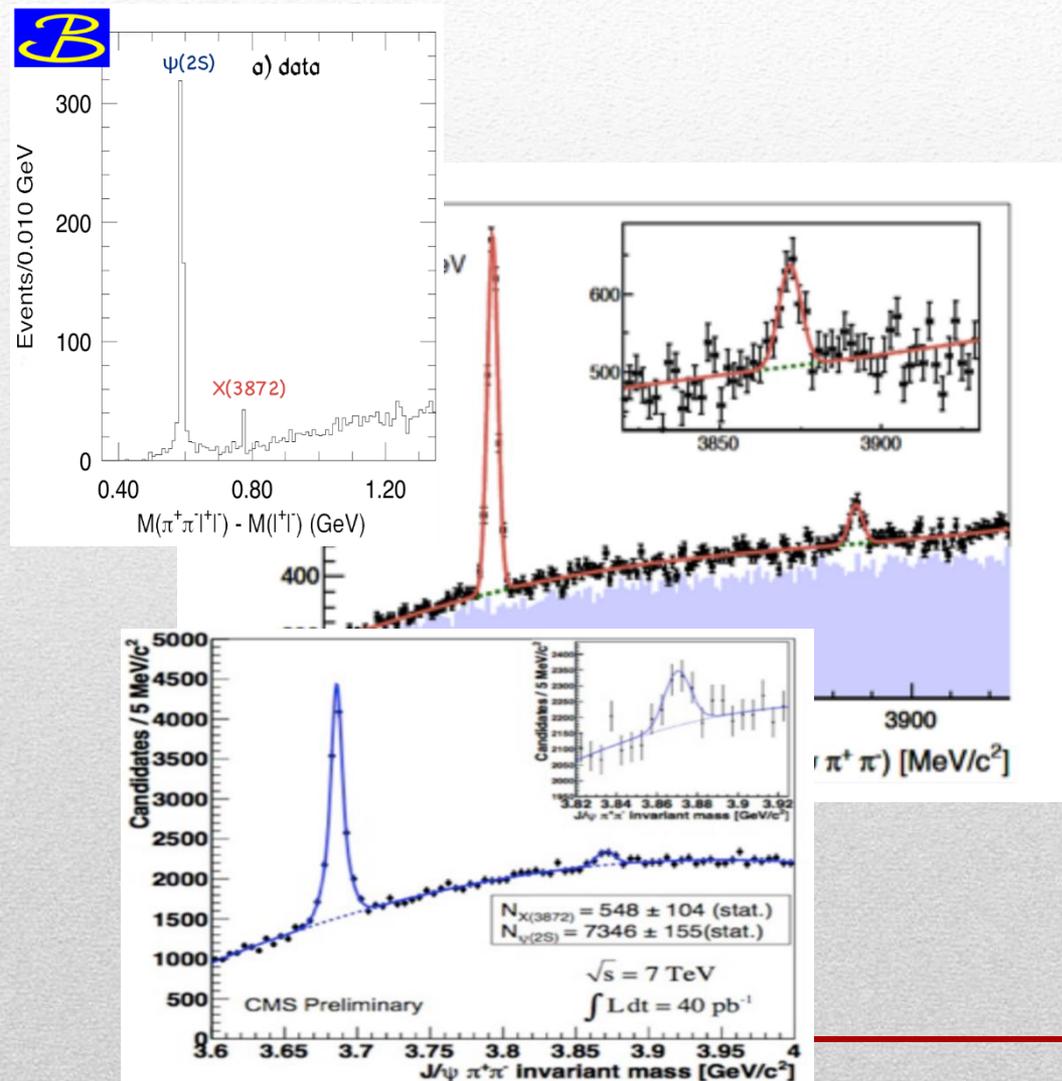

A host of **unexpected resonances** have appeared

decaying mostly into charmonium + light

Hardly reconciled with usual charmonium interpretation

# X(3872)

- Discovered in  $B \rightarrow K X \rightarrow K J/\psi \pi \pi$
- Quantum numbers  $1^{++}$
- **Very close** to  $DD^*$  threshold
- **Too narrow** for an above-threshold charmonium
- **Isospin violation** too big  $\frac{\Gamma(X \rightarrow J/\psi \omega)}{\Gamma(X \rightarrow J/\psi \rho)} \sim 0.8 \pm 0.3$
- **Mass** prediction not compatible with  $\chi_{c1}(2P)$

$$M = 3871.68 \pm 0.17 \text{ MeV}$$

$$M_X - M_{DD^*} = -3 \pm 192 \text{ keV}$$

$$\Gamma < 1.2 \text{ MeV @90\%}$$

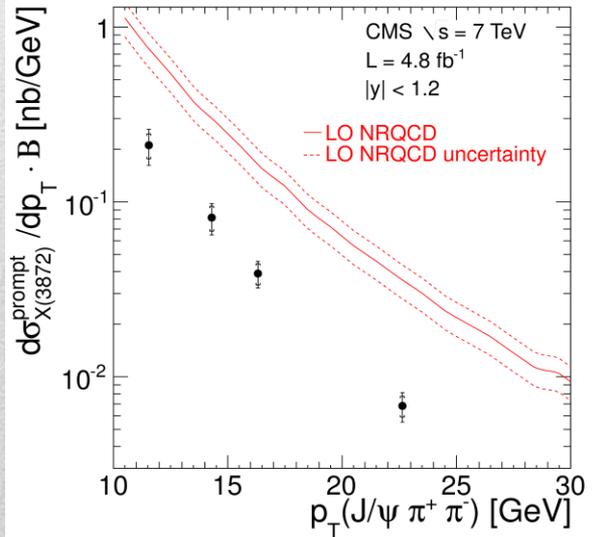

# X(3872)

Large prompt production  
at hadron colliders

$$\sigma_B/\sigma_{TOT} = (26.3 \pm 2.3 \pm 1.6)\%$$

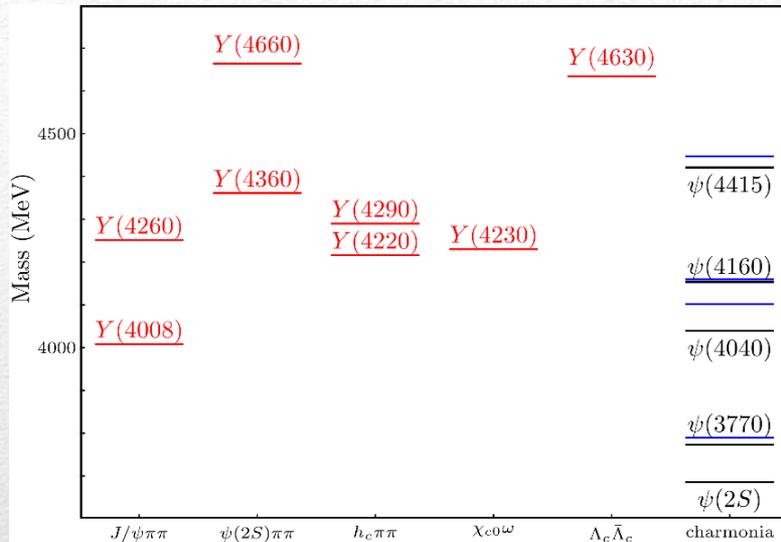

$$\sigma_{PR} \times B(X \rightarrow J/\psi\pi\pi) = (1.06 \pm 0.11 \pm 0.15) \text{ nb}$$

# Vector $Y$ states

Lots of unexpected  $J^{PC} = 1^{--}$  states found in ISR/direct production (and nowhere else!)  
 Seen in few final states, mostly  $J/\psi\pi\pi$  and  $\psi(2S)\pi\pi$

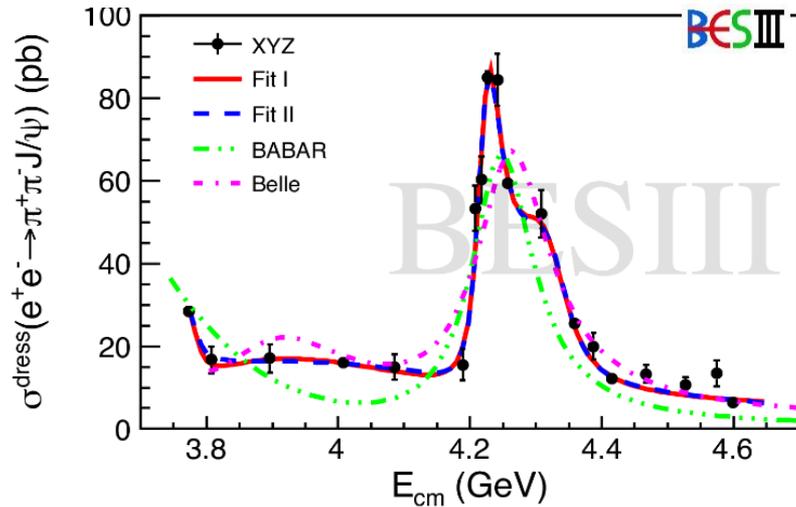

Not seen decaying into open charm pairs  
 Large HQSS violation

# Vector $Y$ states in BESIII

BESIII, PRL118, 092002 (2017)

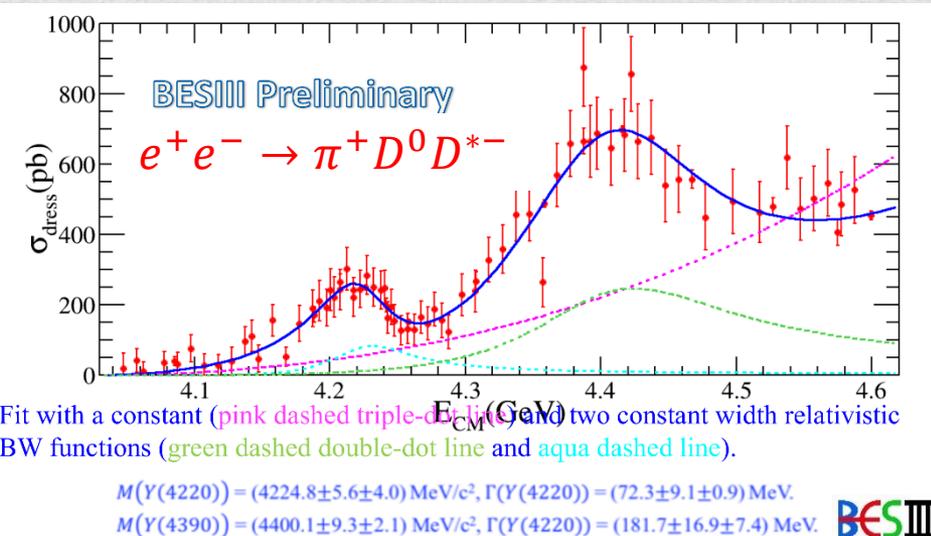

BESIII, PRL118, 092001 (2017)  $e^+e^- \rightarrow J/\psi \pi\pi$

Parameters	Solution I	Solution II
$\Gamma_{e^+e^-} \mathcal{B}[\psi(3770) \rightarrow \pi^+\pi^- J/\psi]$		$0.5 \pm 0.1$ (0)
$\Gamma_{e^+e^-} \mathcal{B}(R_1 \rightarrow \pi^+\pi^- J/\psi)$	$8.8_{-2.2}^{+1.5}$ ( $\dots$ )	$6.8_{-1.5}^{+1.1}$ ( $\dots$ )
$\Gamma_{e^+e^-} \mathcal{B}(R_2 \rightarrow \pi^+\pi^- J/\psi)$	$13.3 \pm 1.4$ ( $12.0 \pm 1.0$ )	$9.2 \pm 0.7$ ( $8.9 \pm 0.6$ )
$\Gamma_{e^+e^-} \mathcal{B}(R_3 \rightarrow \pi^+\pi^- J/\psi)$	$21.1 \pm 3.9$ ( $17.9 \pm 3.3$ )	$1.7_{-0.6}^{+0.8}$ ( $1.1_{-0.4}^{+0.5}$ )
$\phi_1$	$-58 \pm 11$ ( $-33 \pm 8$ )	$-116_{-10}^{+9}$ ( $-81_{-8}^{+7}$ )
$\phi_2$	$-156 \pm 5$ ( $-132 \pm 3$ )	$68 \pm 24$ ( $107 \pm 20$ )

New BESIII data show a peculiar lineshape for the  $Y(4260)$

The state appear lighter and narrower, compatible with the ones in  $h_c \pi\pi$  and  $\chi_{c0} \omega$   
 A broader old-fashioned  $Y(4260)$  is appearing in  $\bar{D}D^* \pi$ , maybe indicating a  $\bar{D}D_1$  dominance

# Charged Z states: $Z_c(3900)$ , $Z_c(4020)$

Charged quarkonium-like resonances have been found, **4q needed**

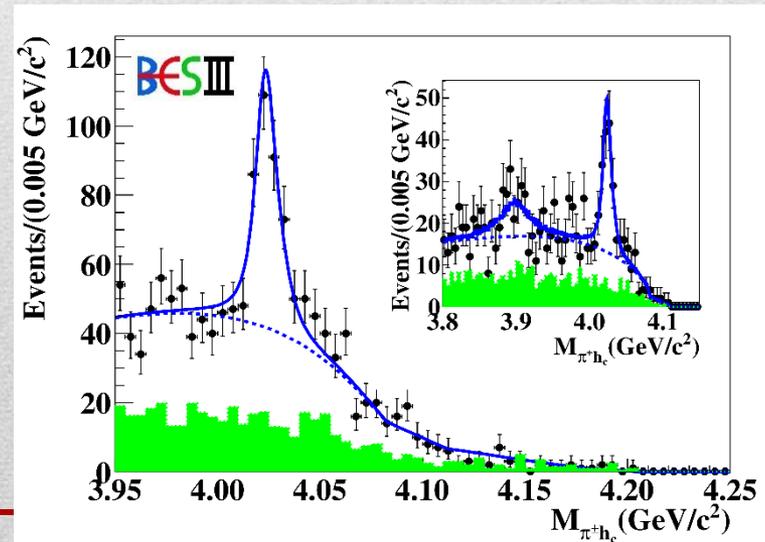

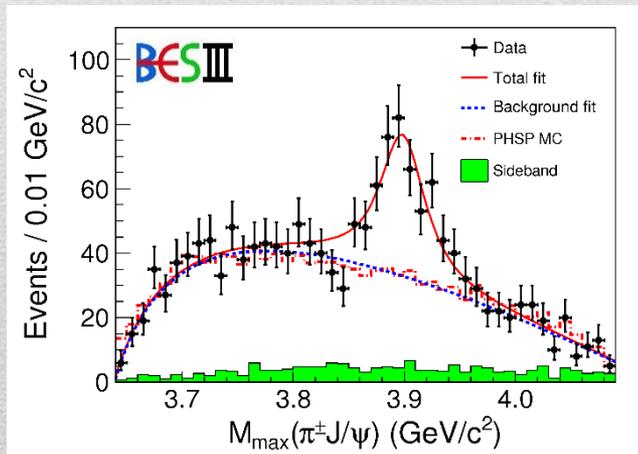

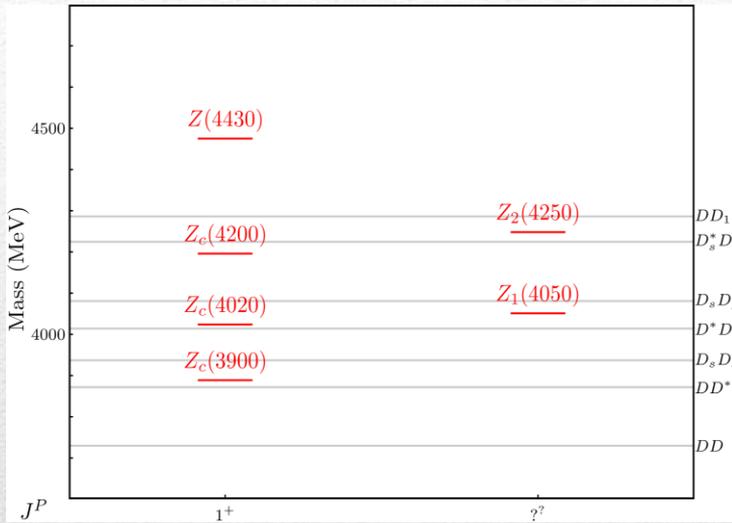

Two states  $J^{PC} = 1^{+-}$  appear  
slightly above  $D^{(*)}D^*$  thresholds

$$e^+e^- \rightarrow Z_c(3900)^+\pi^- \rightarrow J/\psi \pi^+\pi^- \text{ and } (DD^*)^+\pi^-$$

$$M = 3888.7 \pm 3.4 \text{ MeV}, \Gamma = 35 \pm 7 \text{ MeV}$$

$$e^+e^- \rightarrow Z_c'(4020)^+\pi^- \rightarrow h_c \pi^+\pi^- \text{ and } \bar{D}^{*0}D^{*+}\pi^-$$

$$M = 4023.9 \pm 2.4 \text{ MeV}, \Gamma = 10 \pm 6 \text{ MeV}$$

Amplitude analysis

Properties, Model building

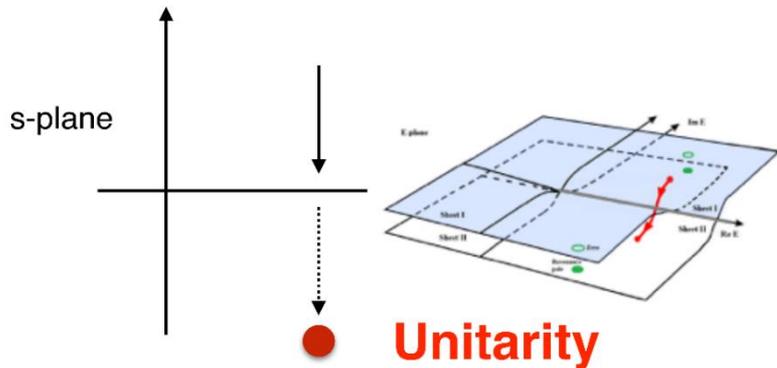

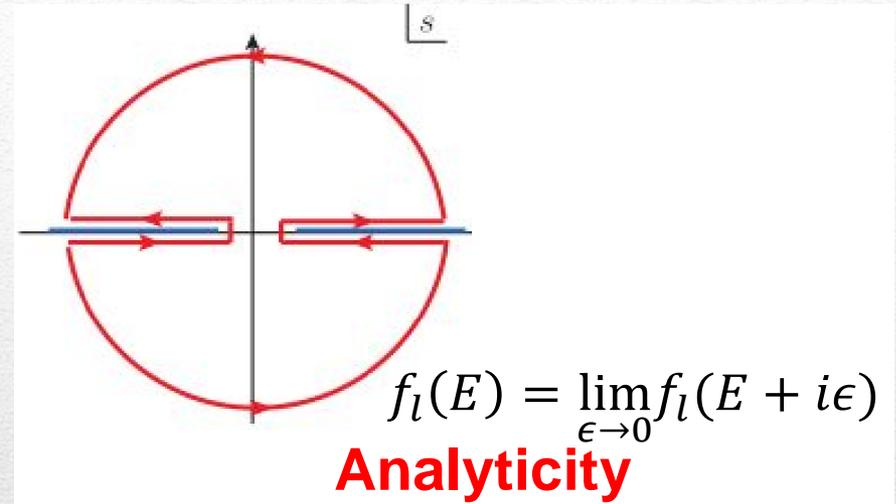

Interpretations on the spectrum leads to understanding fundamental laws of nature

# S-Matrix principles

**Crossing**

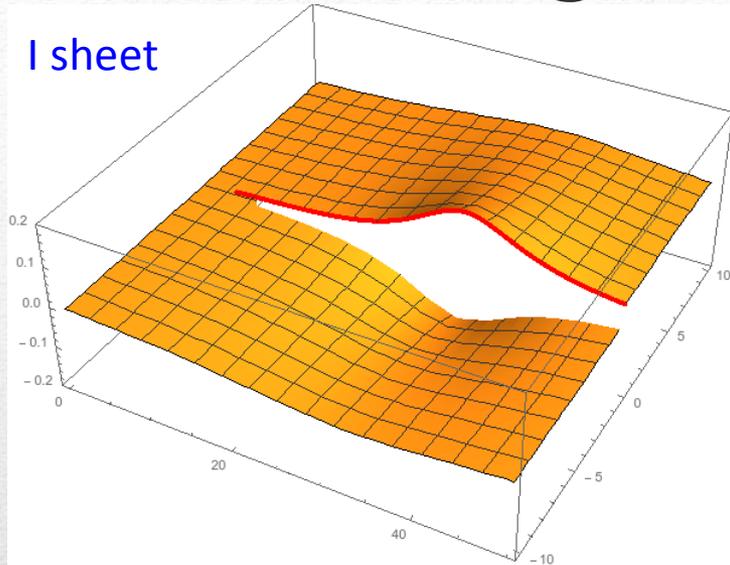

These are constraints the amplitudes have to satisfy, but do not fix the dynamics

Resonances (QCD states) are poles in the unphysical Riemann sheets

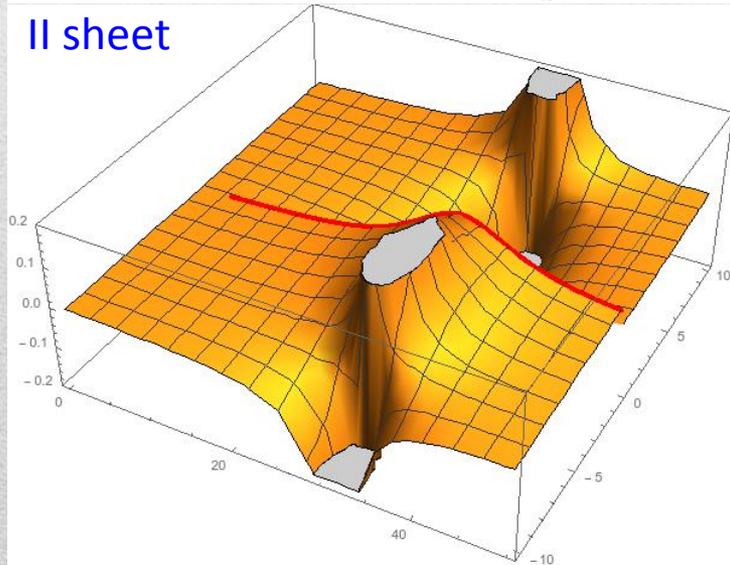

+ Lorentz, discrete & global symmetries

# Pole hunting

I sheet

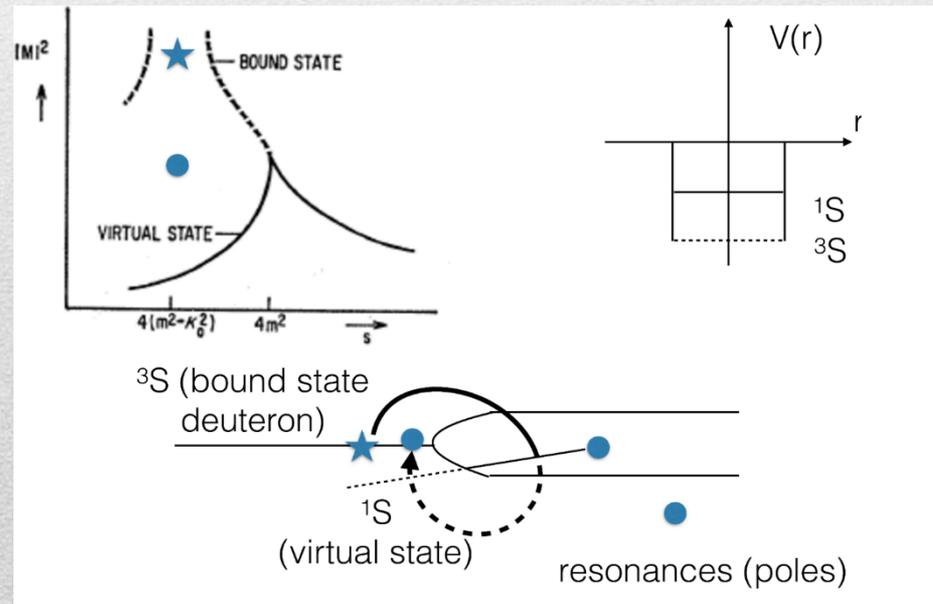

II sheet

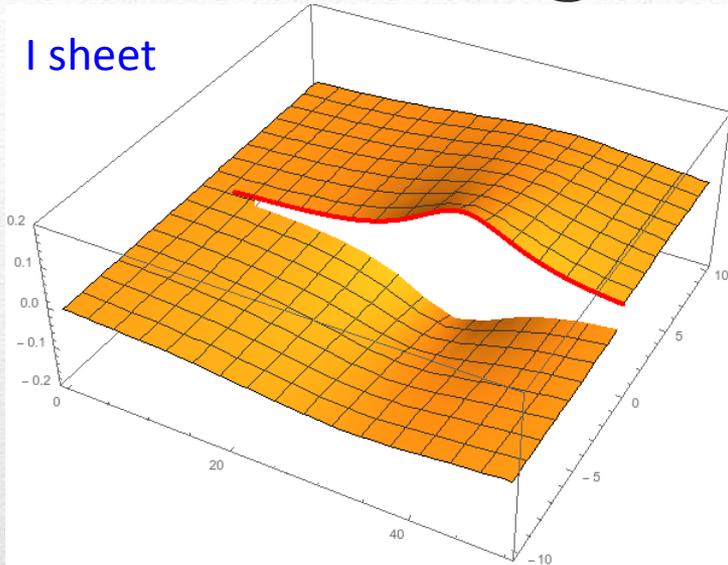

Bound states on the real axis 1st sheet

Not-so-bound (virtual) states on the real axis 2nd sheet

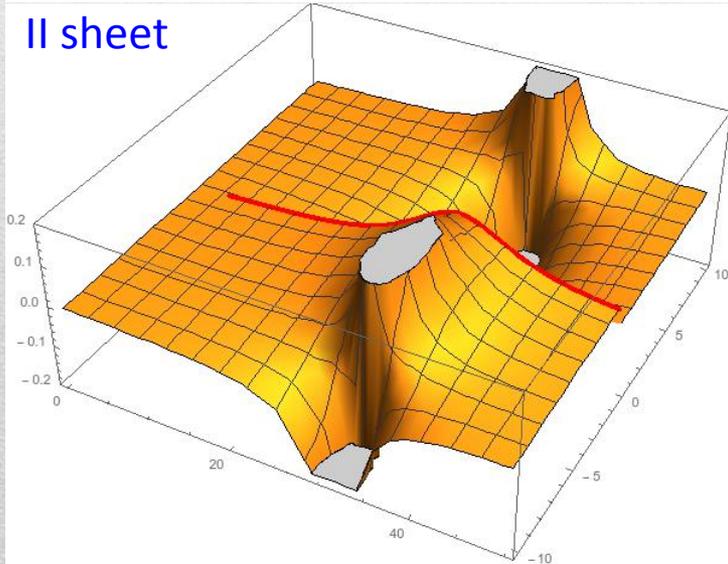

# Pole hunting

I sheet

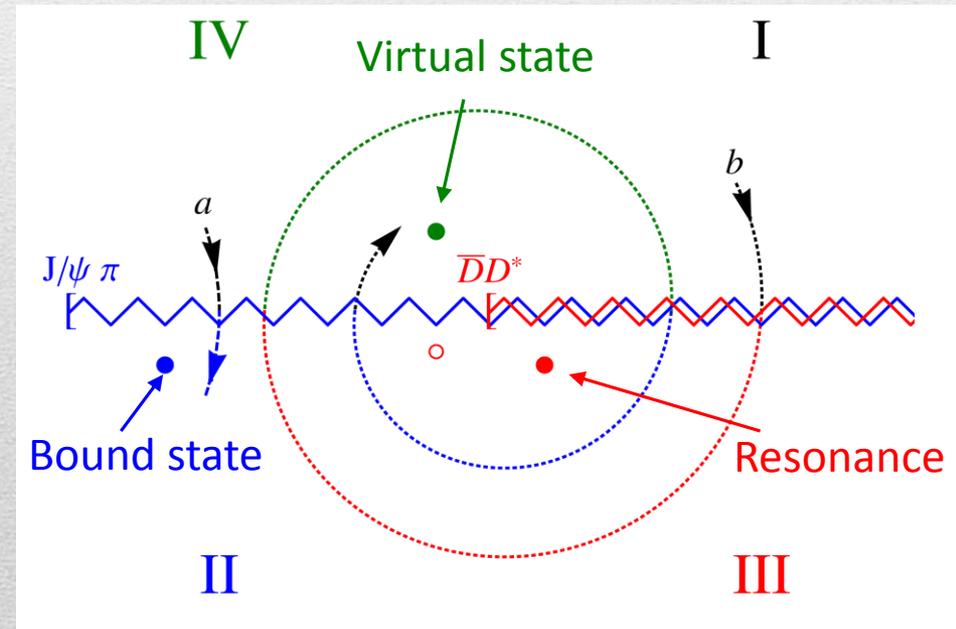

II sheet

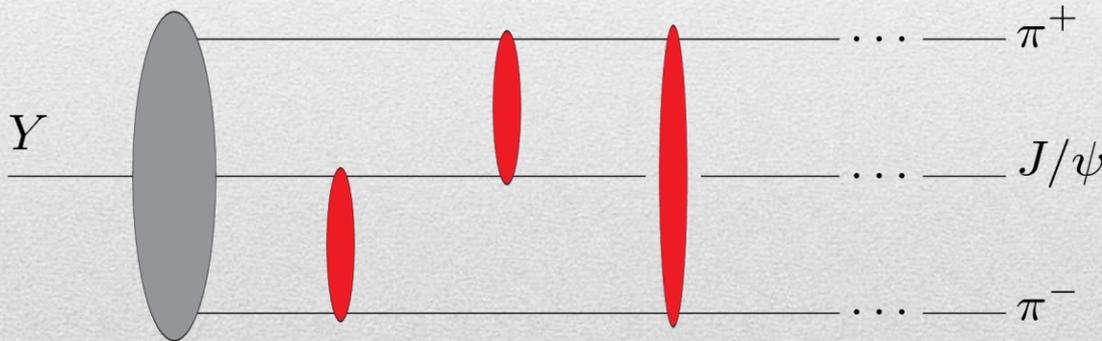

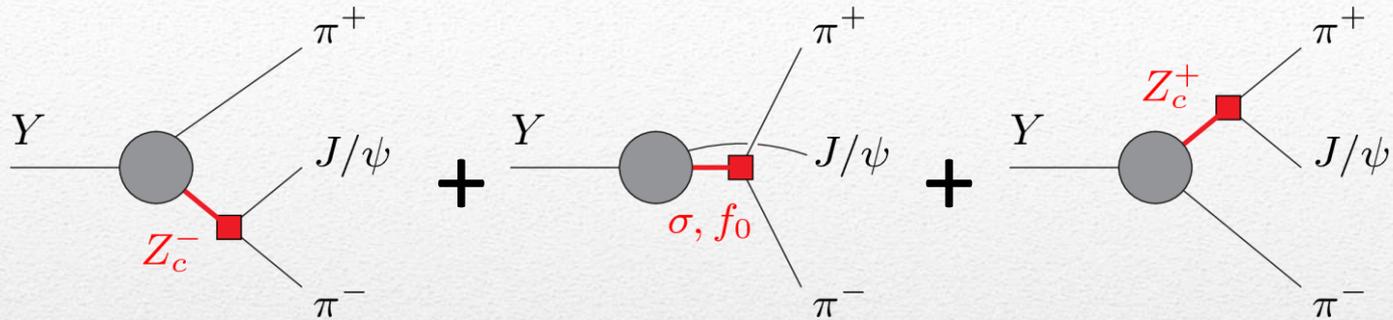

More complicated structure when more thresholds arise:  
two sheets for each new threshold

III sheet: usual resonances  
IV sheet: cusps (virtual states)

# The isobar model

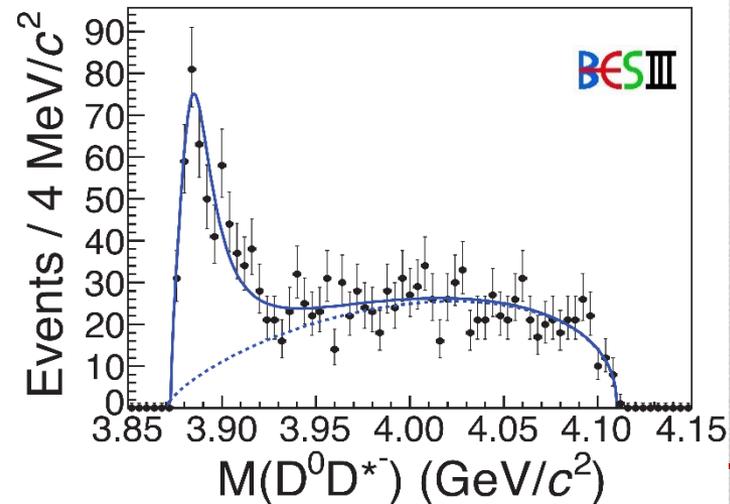

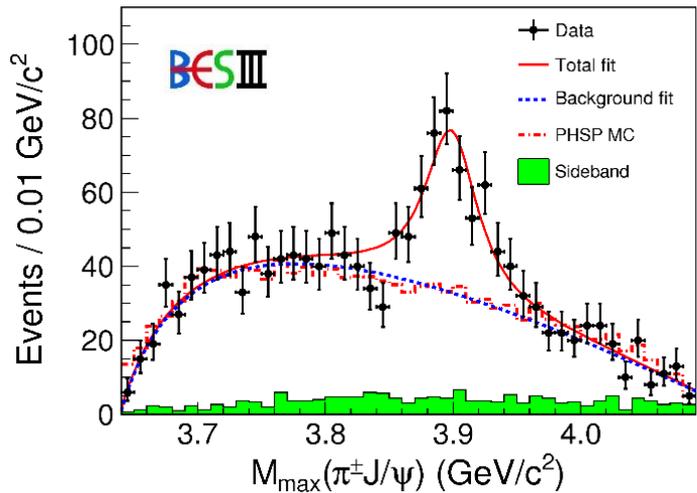

The formalism implements the all-order rescattering in **all the 3 channels at once**

Khuri-Treiman formalism was introduced to describe  $K \rightarrow 3\pi$   
 Khuri and Treiman, PR119, 1115

Used recently for several reactions,  
 Niecknig and Kubis, JHEP 10, 142  
 Colangelo, *et al.*, PRL118, 022001  
 AP *et al.* [JPAC], PLB772, 200  
 Albaladejo, AP *et al.* [JPAC], 1803.06027

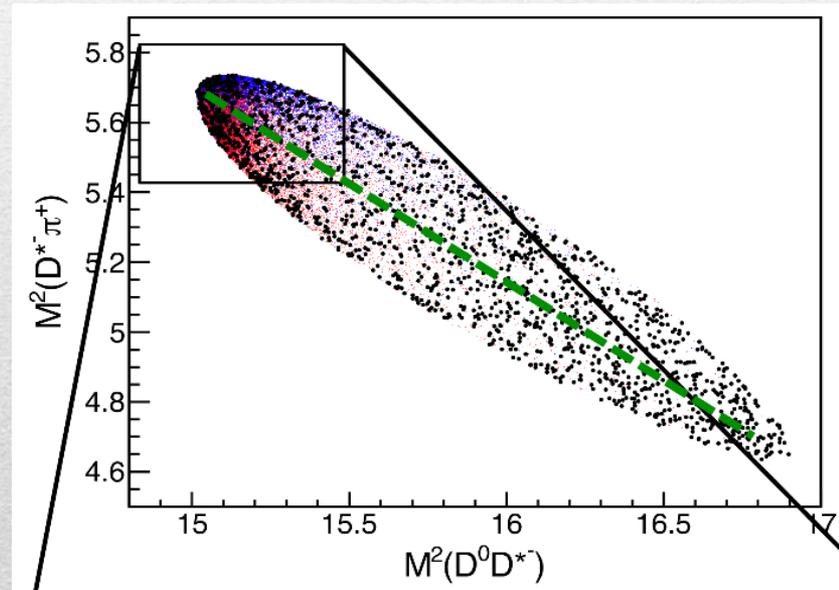

# Example: The charged $Z_c(3900)$

A **charged charmonium-like** resonance has been claimed by BESIII in 2013.

$$e^+e^- \rightarrow Z_c(3900)^+\pi^- \rightarrow J/\psi \pi^+\pi^- \text{ and } \rightarrow (DD^*)^+\pi^-$$

$$M = 3888.7 \pm 3.4 \text{ MeV}, \Gamma = 35 \pm 7 \text{ MeV}$$

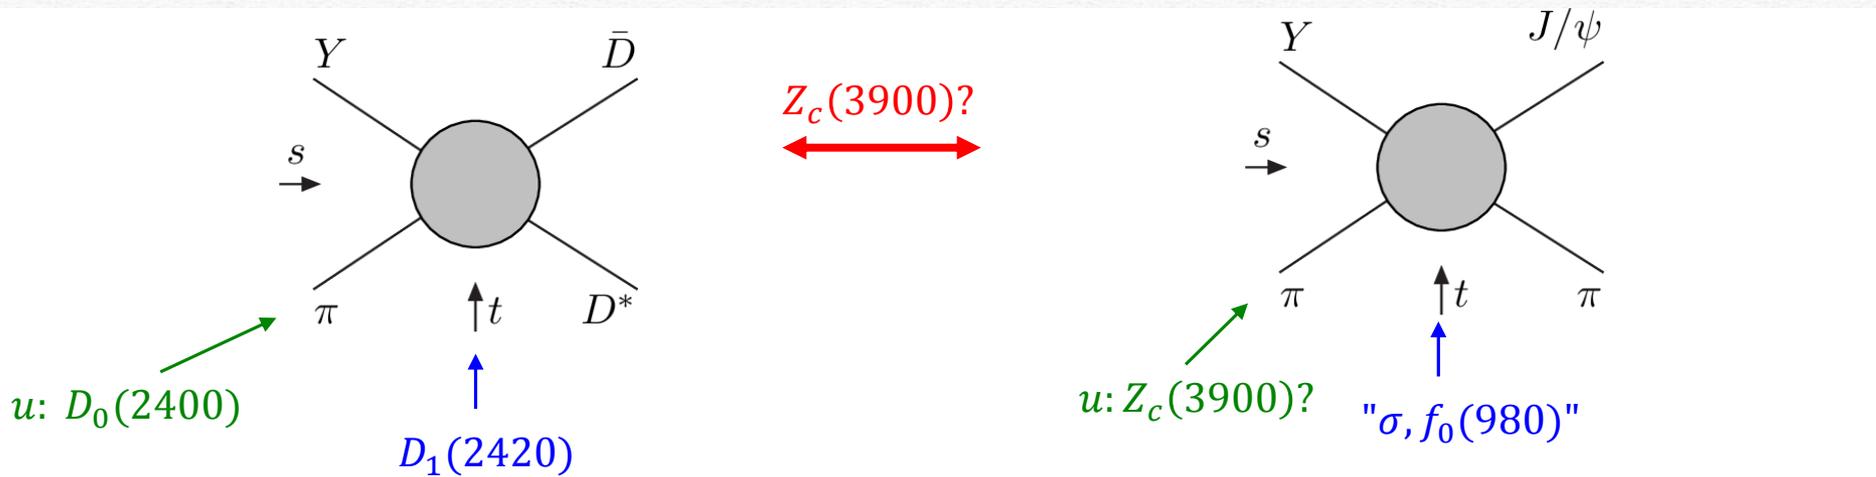

Such a state would require a **minimal 4q content** and would be manifestly exotic

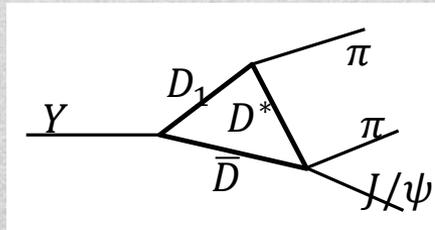

# Amplitude analysis for $Z_c(3900)$

One can test different parametrizations of the amplitude, which correspond to **different singularities**  $\rightarrow$  **different natures**

# Amplitude model

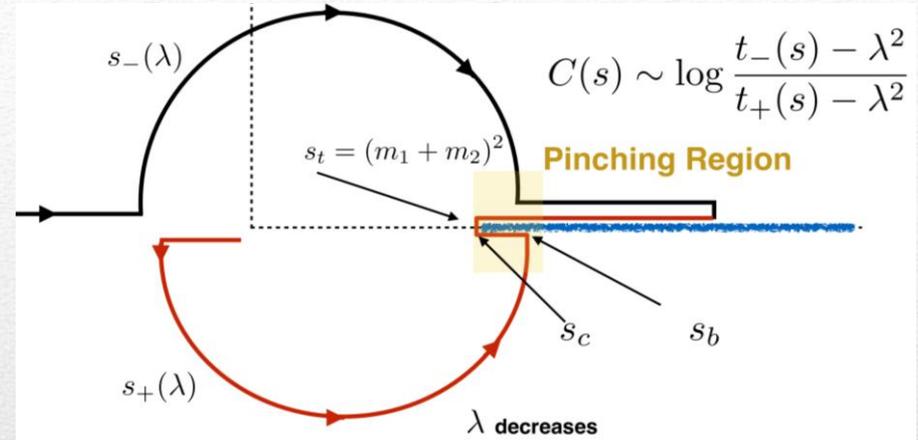

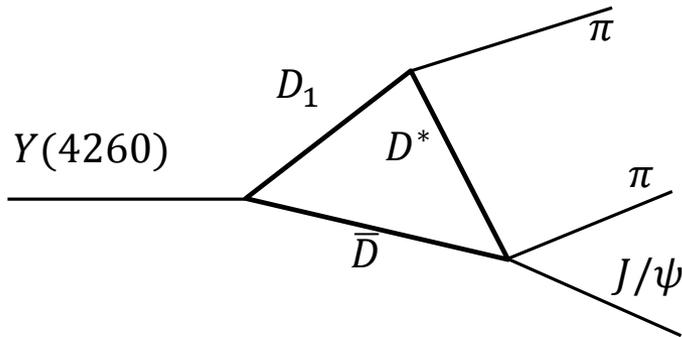

$$f_i(s, t, u) = 16\pi \sum_{l=0}^{L_{\max}} (2l+1) \left( a_{l,i}^{(s)}(s) P_l(z_s) + a_{l,i}^{(t)}(t) P_l(z_t) + a_{l,i}^{(u)}(u) P_l(z_u) \right)$$

$$f_{0,i}(s) = \frac{1}{32\pi} \int_{-1}^1 dz_s f_i(s, t(s, z_s), u(s, z_s)) = a_{0,i}^{(s)} + \frac{1}{32\pi} \int_{-1}^1 dz_s \left( a_{0,i}^{(t)}(t) + a_{0,i}^{(u)}(u) \right) \equiv a_{0,i}^{(s)} + b_{0,i}(s)$$

$$f_{l,i}(s) = \frac{1}{32\pi} \int_{-1}^1 dz_s P_l(z_s) \left( a_{0,i}^{(t)}(t) + a_{0,i}^{(u)}(u) \right) \equiv b_{l,i}(s) \quad \text{for } l > 0. \quad f_{0,i}(s) = b_{0,i}(s) + \sum_j t_{ij}(s) \frac{1}{\pi} \int_{s_j}^{\infty} ds' \frac{\rho_j(s') b_{0,j}(s')}{s' - s},$$

$$f_i(s, t, u) = 16\pi \left[ a_{0,i}^{(t)}(t) + a_{0,i}^{(u)}(u) + \sum_j t_{ij}(s) \left( c_j + \frac{s}{\pi} \int_{s_j}^{\infty} ds' \frac{\rho_j(s') b_{0,j}(s')}{s' (s' - s)} \right) \right],$$

# Triangle singularity

Logarithmic branch points due to exchanges in the cross channels can simulate a resonant behavior, only in **very special kinematical conditions** (Coleman and Norton, *Nuovo Cim.* 38, 438), However, this effects **cancel in Dalitz projections, no peaks** (Schmid, *Phys.Rev.* 154, 1363)

$$f_{0,i}(s) = b_{0,i}(s) + \frac{t_{ij}}{\pi} \int_{s_i}^{\infty} ds' \frac{\rho_j(s') b_{0,j}(s')}{s' - s}$$

...but the cancellation can be spread in different channels, you might still see peaks in other channels only!

Szczepaniak, PLB747, 410-416

Szczepaniak, PLB757, 61-64

Guo, Meissner, Wang, Yang PRD92, 071502

# Testing scenarios

- We approximate all the particles to be scalar – this affects the value of couplings, which are not normalized anyway – but not the position of singularities. This also limits the number of free parameters

$$f_i(s, t, u) = 16\pi \left[ a_{0,i}^{(t)}(t) + a_{0,i}^{(u)}(u) + \sum_j t_{ij}(s) \left( c_j + \frac{s}{\pi} \int_{s_j}^{\infty} ds' \frac{\rho_j(s') b_{0,j}(s')}{s' (s' - s)} \right) \right],$$

The scattering matrix is parametrized as  $(t^{-1})_{ij} = K_{ij} - i \rho_i \delta_{ij}$

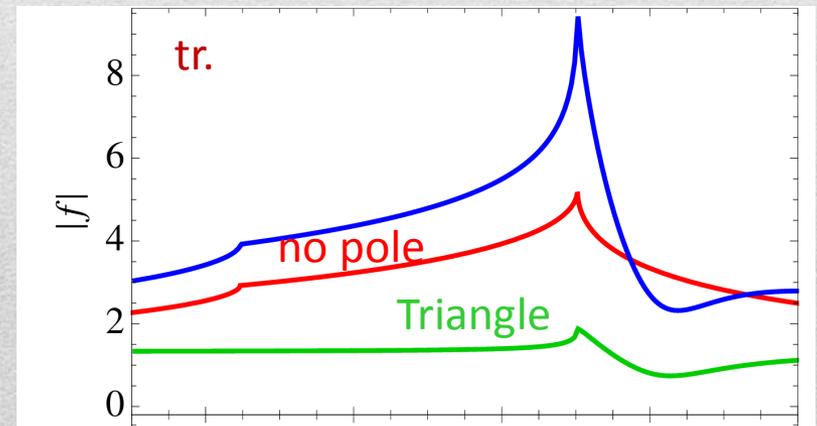

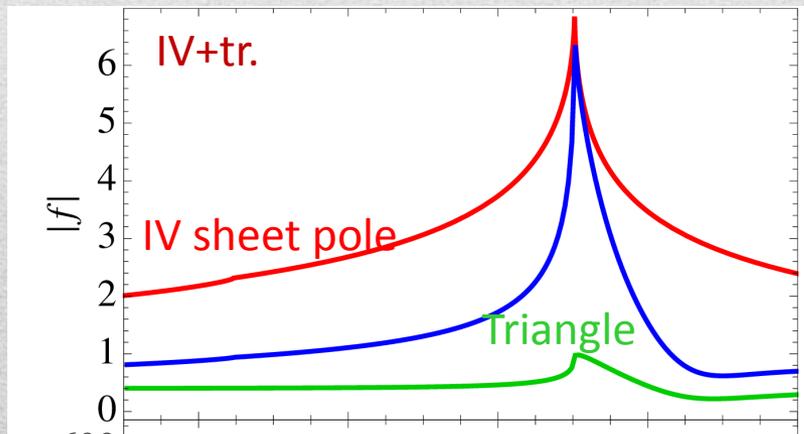

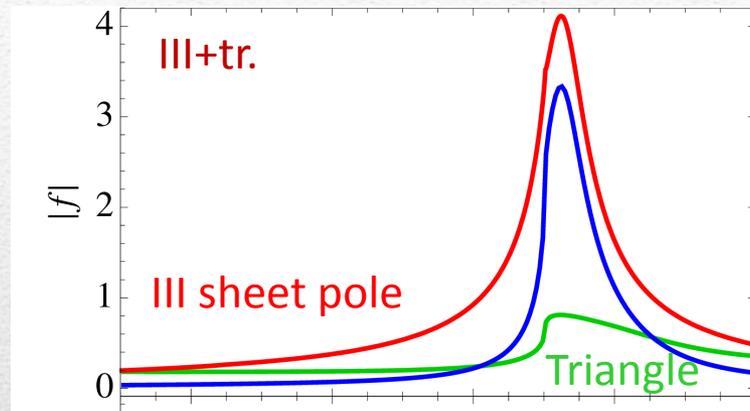

Four different scenarios considered:

- «III»: the K matrix is  $\frac{g_i g_j}{M^2 - s}$ , this generates a pole in the closest unphysical sheet the rescattering integral is set to zero
- «III+tr.»: same, but with the correct value of the rescattering integral
- «IV+tr.»: the K matrix is constant, this generates a pole in the IV sheet
- «tr.»: same, but the pole is pushed far away by adding a penalty in the  $\chi^2$

# Searching for resonances in $\eta\pi$

- The  $\eta\pi$  system is one of the golden modes for hunting **hybrid mesons**
- We build the partial wave amplitudes according to the  **$N/D$  method**
- We test against the  $D$ -wave data, where the  $a_2$  and the  $a'_2$  show up

A. Jackura, M. Mikhasenko, *AP et al.* (JPAC & COMPASS), PLB779, 464-472

## Production amplitude

$$\text{Im} \mathbb{P} = \sum_n \text{Im} \mathbb{P} \left( \text{Diagram with } n \text{ intermediate states} \right)$$

The diagram shows the imaginary part of the production amplitude  $\text{Im} \mathbb{P}$  as a sum over  $n$  intermediate states. The left side shows a vertex where an incoming  $\pi^-$  and an incoming  $P$  (wavy line) meet, producing an  $\eta$  and a  $\pi^-$ . The right side shows a similar vertex, but with  $n$  intermediate states (represented by wavy lines) between the production vertex and a scattering vertex. The scattering vertex produces an  $\eta$  and a  $\pi^-$ . The sum is over  $n$ , and the final state is labeled  $s, L, M$ .

## Scattering amplitude

$$\text{Im} \mathbb{P} = \sum_n \text{Im} \mathbb{P} \left( \text{Diagram with } n \text{ intermediate states} \right)$$

The diagram shows the imaginary part of the scattering amplitude  $\text{Im} \mathbb{P}$  as a sum over  $n$  intermediate states. The left side shows a vertex where an incoming  $\eta$  and an incoming  $\pi^-$  meet, producing an  $\eta$  and a  $\pi^-$ . The right side shows a similar vertex, but with  $n$  intermediate states (represented by wavy lines) between the production vertex and a scattering vertex. The scattering vertex produces an  $\eta$  and a  $\pi^-$ . The sum is over  $n$ , and the final state is labeled  $s, L, M$ .

# Searching for resonances in $\eta\pi$

- The  $\eta\pi$  system is one of the golden modes for hunting **hybrid mesons**
- We build the partial wave amplitudes according to the  **$N/D$  method**
- We test against the  $D$ -wave data, where the  $a_2$  and the  $a'_2$  show up

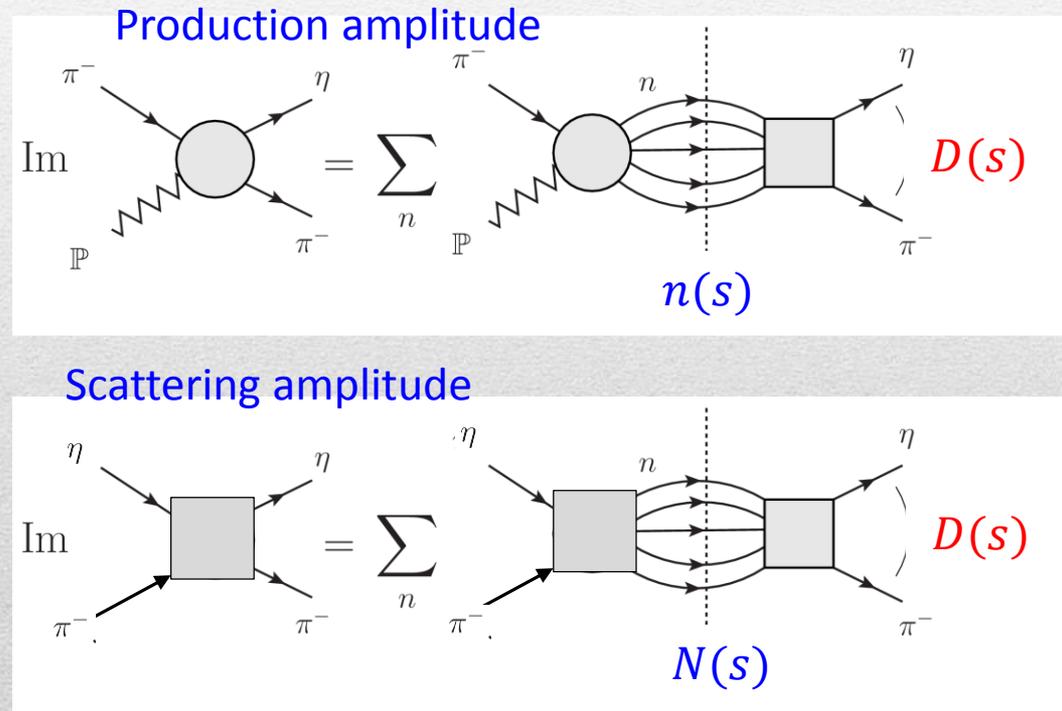

A. Jackura, M. Mikhasenko, *AP et al.* (JPAC & COMPASS), PLB779, 464-472

$$t(s) = \frac{N(s)}{D(s)}$$

The  $D(s)$  has **only right hand cuts**;  
it contains all the Final State Interactions  
constrained by unitarity  $\rightarrow$  **universal**

$$\text{Im } D(s) = -\rho N(s)$$

# Searching for resonances in $\eta\pi$

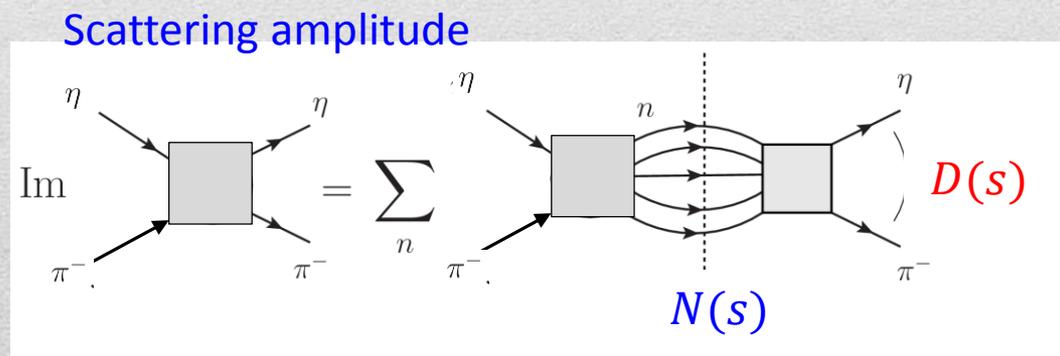

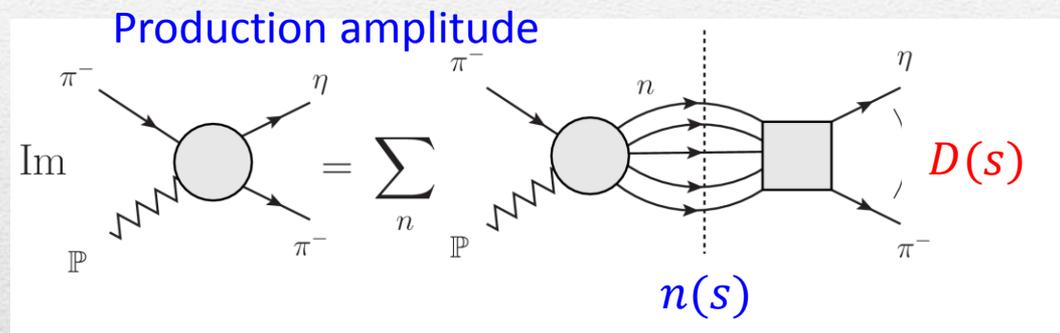

- The  $\eta\pi$  system is one of the golden modes for hunting **hybrid mesons**
- We build the partial wave amplitudes according to the  **$N/D$  method**
- We test against the  $D$ -wave data, where the  $a_2$  and the  $a'_2$  show up

A. Jackura, M. Mikhasenko, *AP et al.* (JPAC & COMPASS), PLB779, 464-472

$$t(s) = \frac{N(s)}{D(s)}$$

The  $n(s)$ ,  $N(s)$  have **left hand cuts only**, they depend on the exchanges  $\rightarrow$  **process-dependent, smooth**

# Searching for resonances in $\eta\pi$

The denominator  $D(s)$  contains all the FSI constrained by unitarity  $\rightarrow$  **universal**

$$D(s) = (K^{-1})(s) - \frac{s}{\pi} \int_{s_i}^{\infty} \frac{\rho(s')N(s')}{s'(s'-s)} ds'$$

$$K(s) = \sum_R \frac{g_R^2}{M_R^2 - s} \quad \text{OR} \quad K^{-1}(s) = c_0 - c_1 s + \sum_i \frac{c_i}{M_i^2 - s}$$

$$\rho(s)N(s) = g \frac{\lambda^{(2l+1)/2}(s, m_\pi^2, m_\eta^2)}{(s + s_R)^7}$$

# Searching for resonances in $\eta\pi$

The denominator  $D(s)$  contains all the FSI constrained by unitarity  $\rightarrow$  **universal**

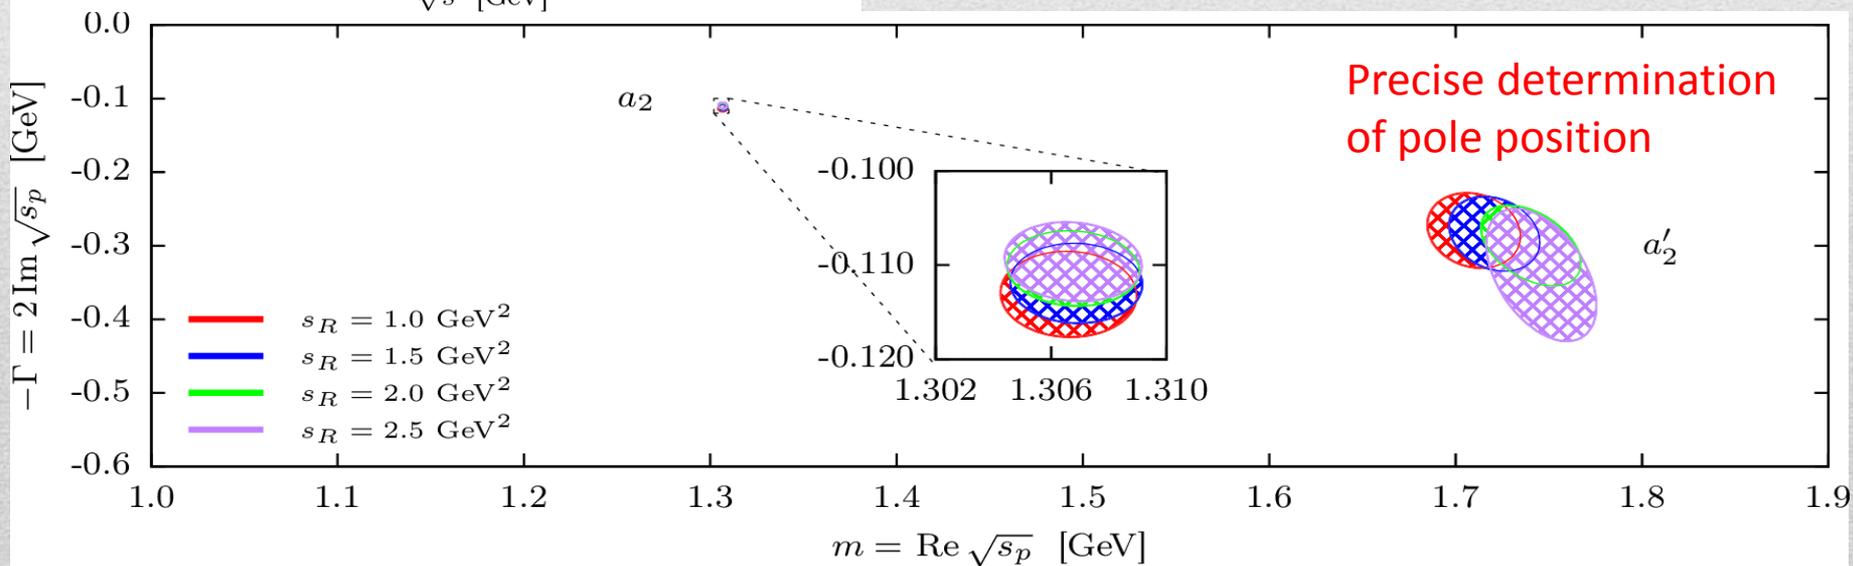

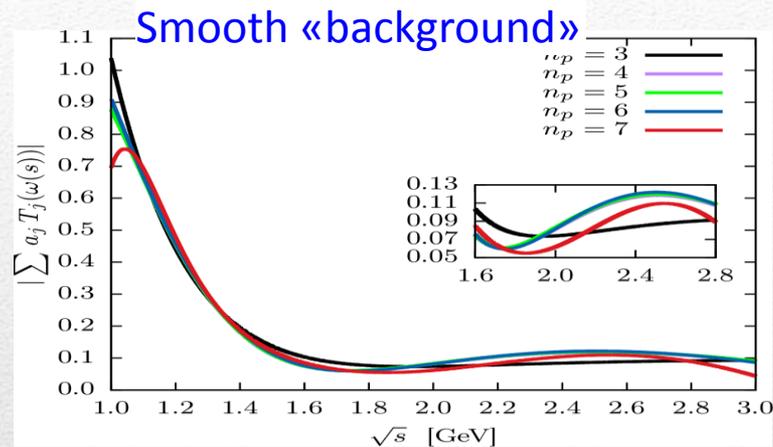

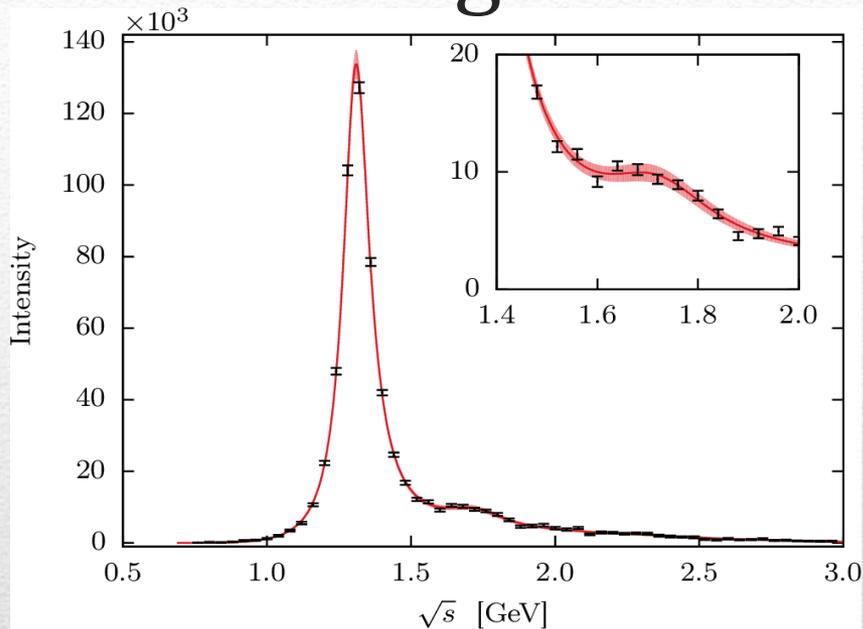

$$D(s) = (K^{-1})(s) - \frac{s}{\pi} \int_{s_i}^{\infty} \frac{\rho(s')N(s')}{s'(s'-s)} ds'$$

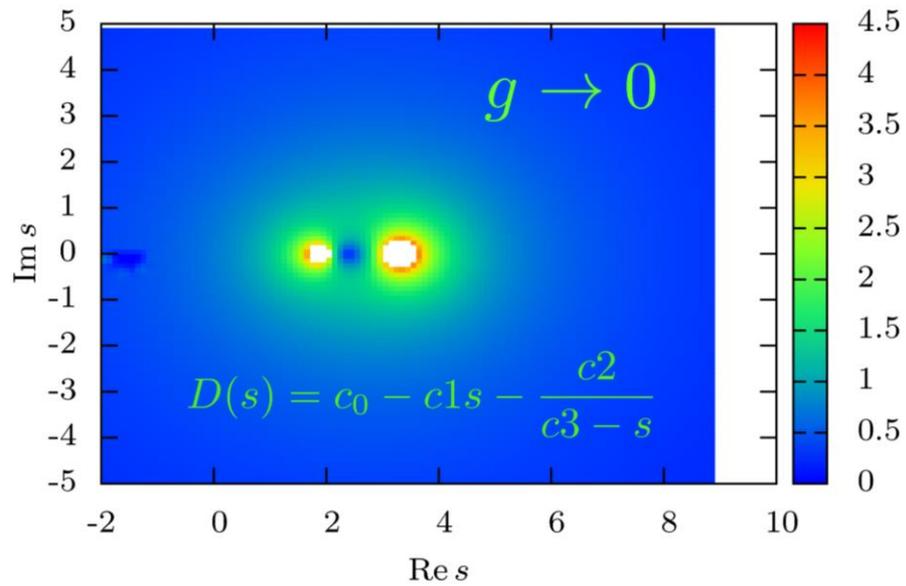

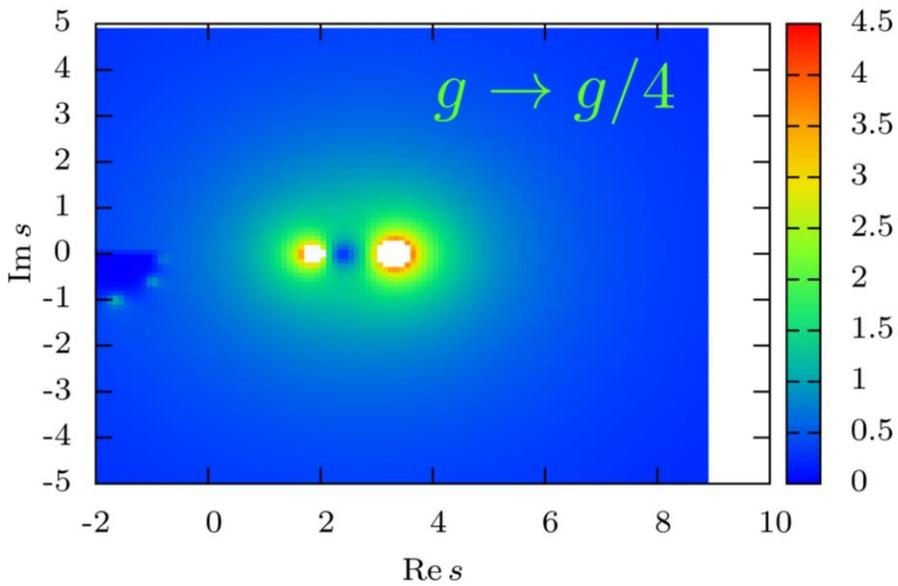

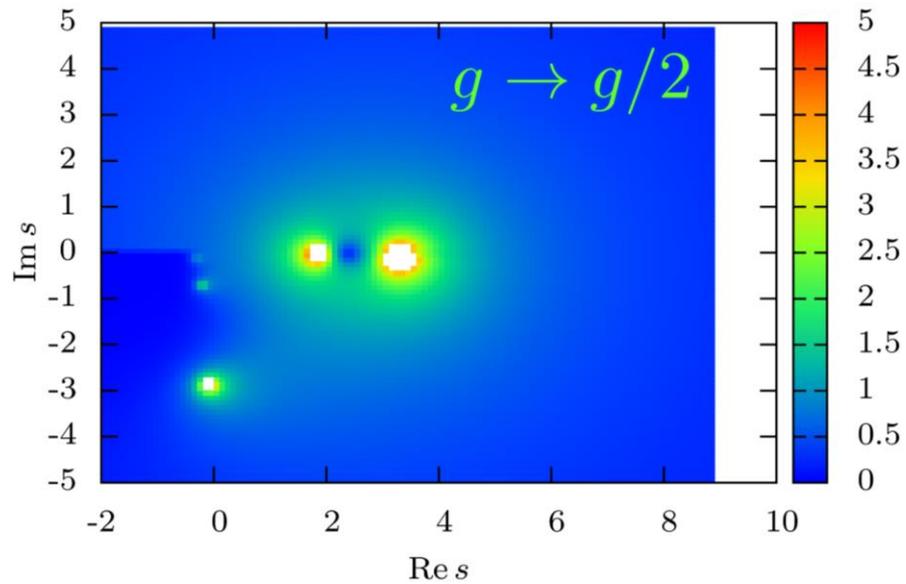

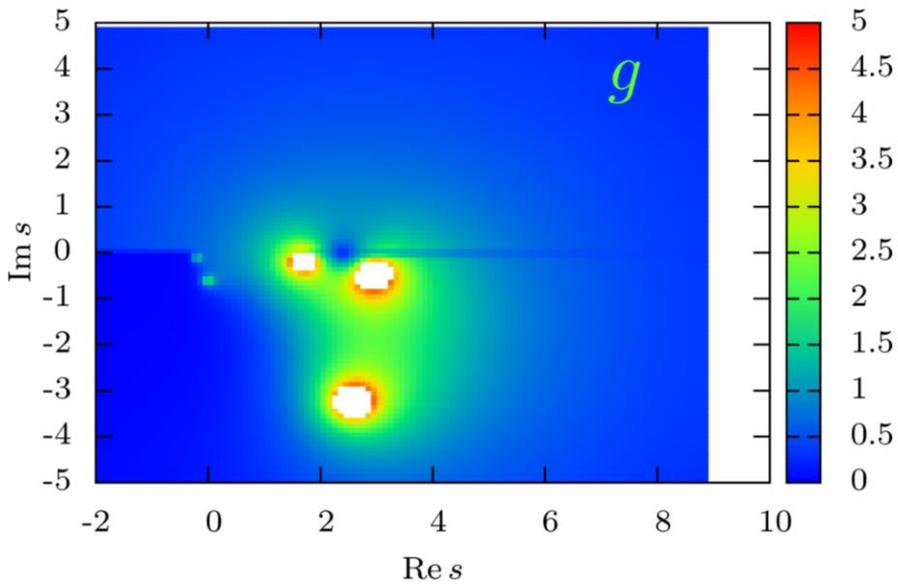

$$K(s) = \sum_R \frac{g_R^2}{M_R^2 - s} \quad \text{OR} \quad K^{-1}(s) = c_0 - c_1 s + \sum_i \frac{c_i}{M_i^2 - s}$$

The  $n(s)$  is **process-dependent, smooth**

$$n(s) = \sum_j a_j T_j(\omega(s)) \quad \omega(s) = \frac{s}{s + s_0}$$

# Searching for resonances in $\eta\pi$

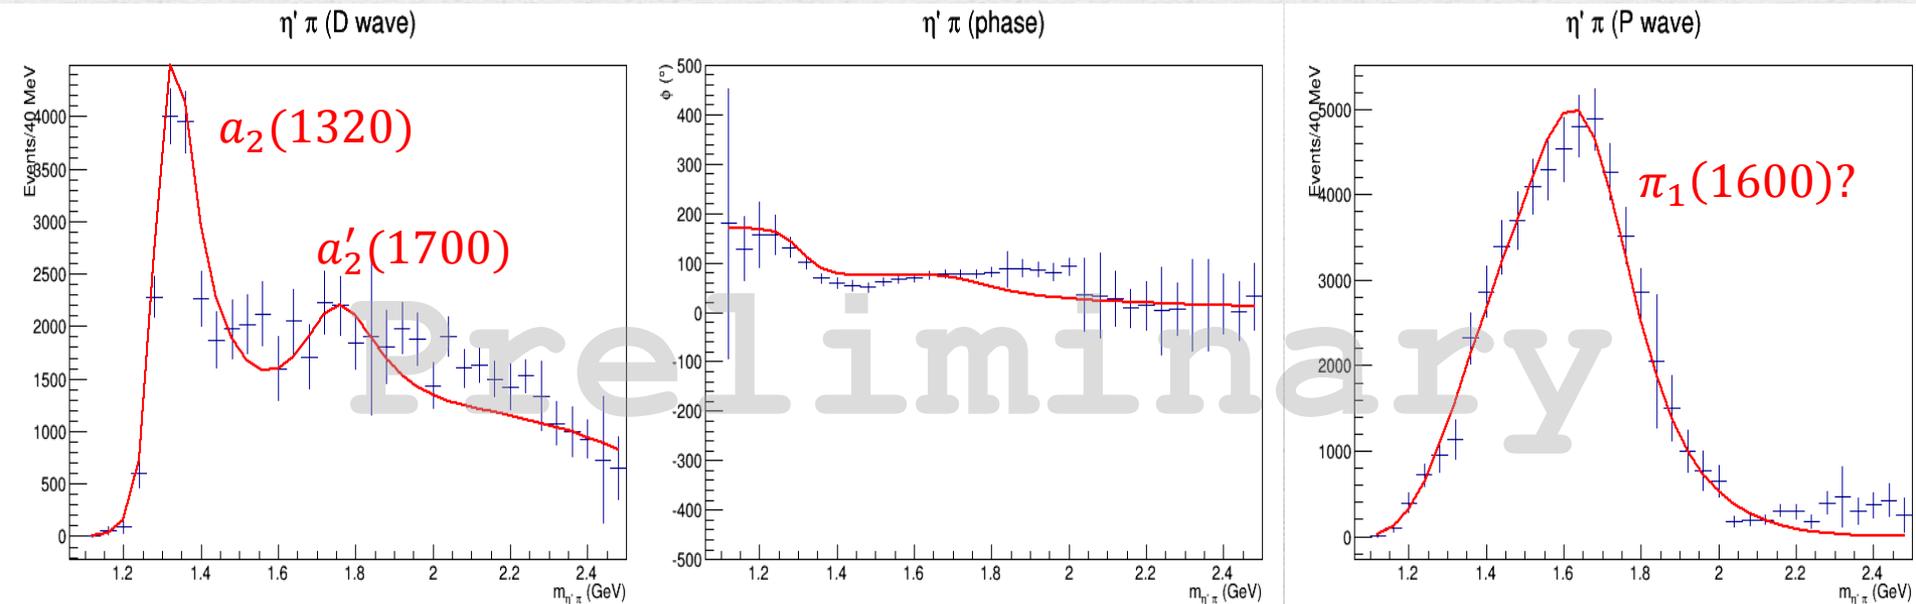

# Searching for resonances in $\eta\pi$

$$m(a_2) = (1307 \pm 1 \pm 6) \text{ MeV} \quad m(a'_2) = (1720 \pm 10 \pm 60) \text{ MeV}$$
$$\Gamma(a_2) = (112 \pm 1 \pm 8) \text{ MeV} \quad \Gamma(a'_2) = (280 \pm 10 \pm 70) \text{ MeV}$$

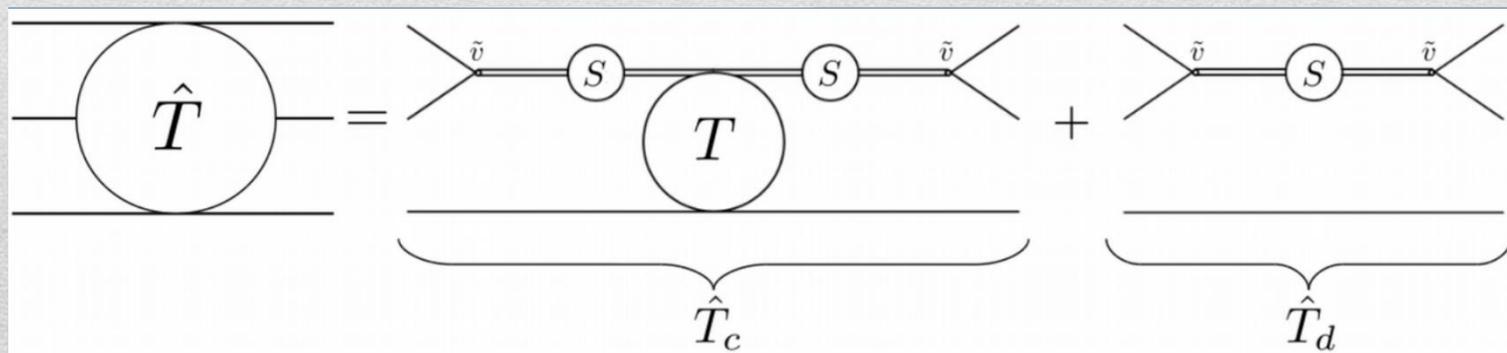

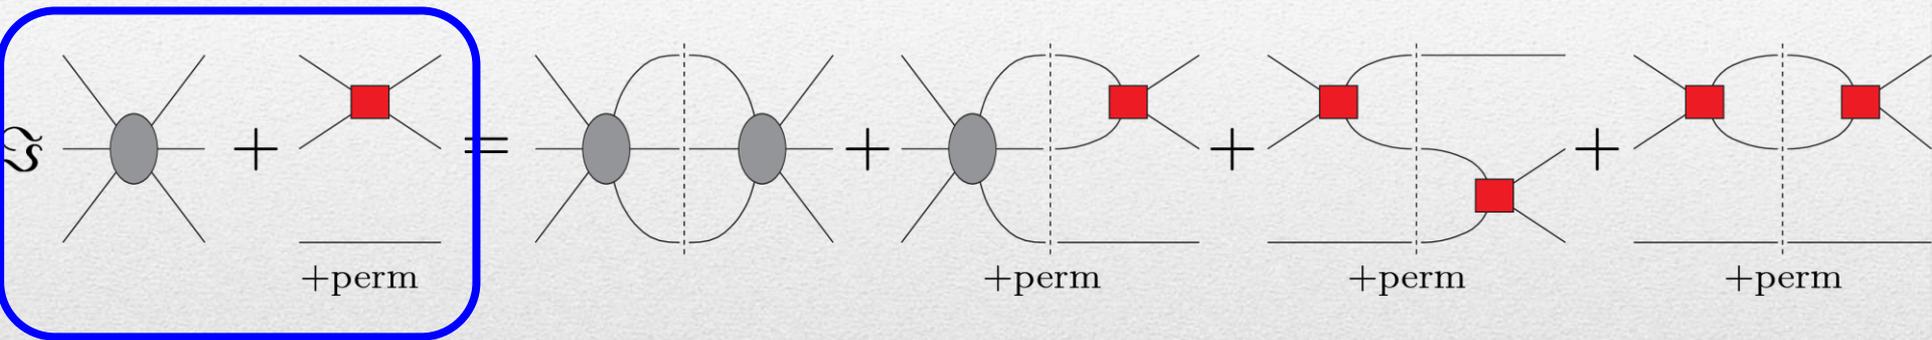

- The **coupled channel analysis** involving the **exotic  $P$ -wave** is **ongoing**, as well as the extension to the GlueX production mechanism and kinematics

# Three-Body Unitarity

Glueball

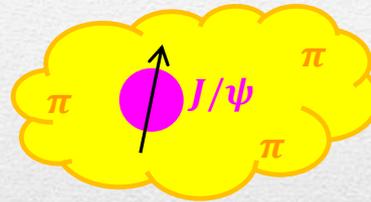

Hybrids

Tetraquark

Molecule

Hadroquarkonium

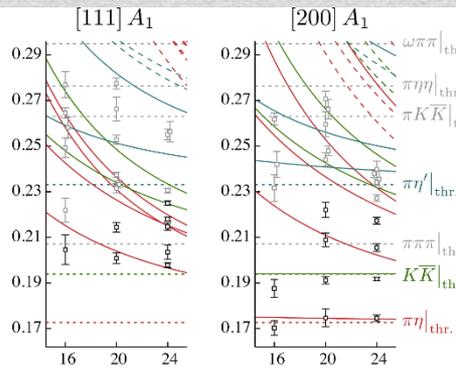

Experiment

Lattice QCD

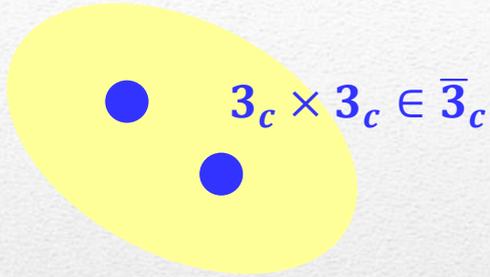

Interpretations on the spectrum leads to understanding fundamental laws of nature

# Diquarks

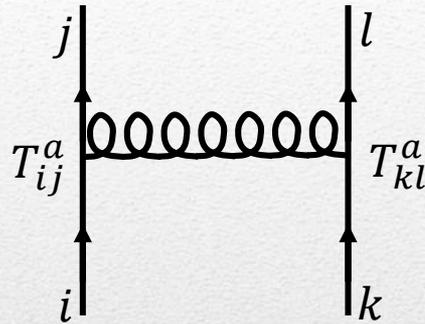

Attraction and repulsion in 1-gluon exchange approximation is given by

$$R = \frac{1}{2} (C_2(R_{12}) - C_2(R_1) - C_2(R_2))$$

$$R_1 = -\frac{4}{3}, R_8 = +\frac{1}{6}$$

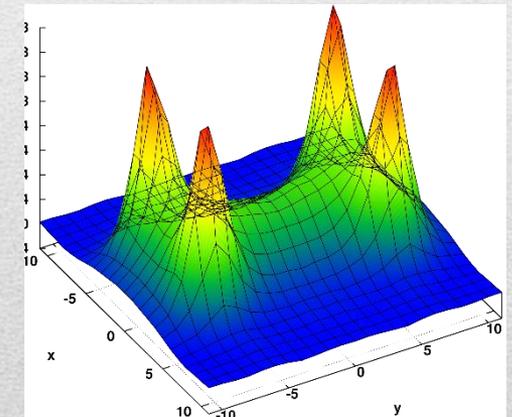

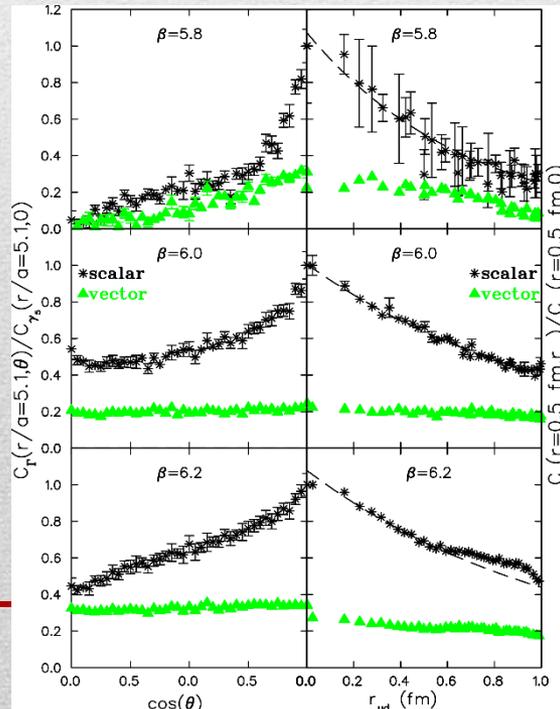

$$R_3 = -\frac{2}{3}, R_6 = +\frac{1}{3}$$

The singlet  $\mathbf{1}_c$  is attractive

A diquark in  $\bar{\mathbf{3}}_c$  is attractive

Evidence (?) of diquarks in LQCD,  
Alexandrou, de Forcrand, Lucini,  
PRL 97, 222002

H-shape with a 4 quark system  
Cardoso, Cardoso, Bicudo,  
PRD84, 054508

# Tetraquark

In a constituent (di)quark model, we can think of a **diquark-antidiquark compact state**

$$[cq]_{S=0}[\bar{c}\bar{q}]_{S=1} + h.c.$$

Maiani, Piccinini, Polosa, Riquer PRD71 014028

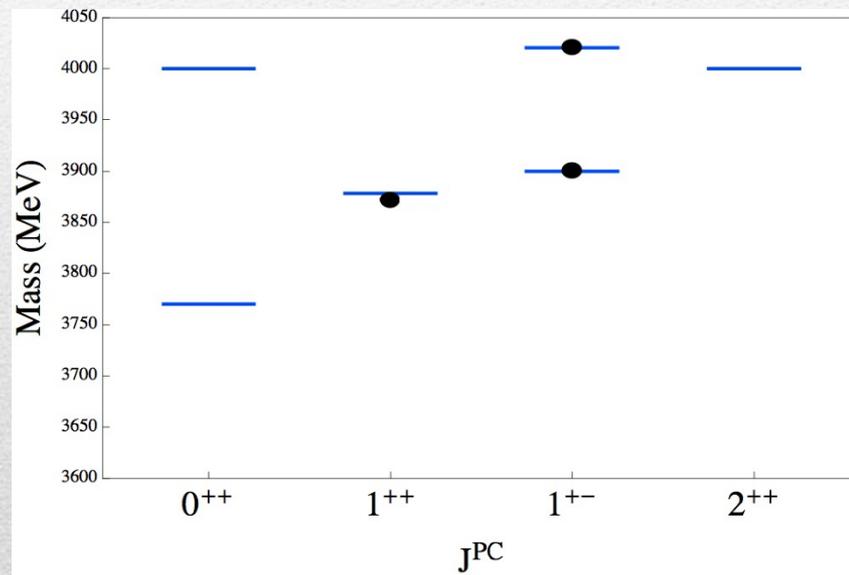

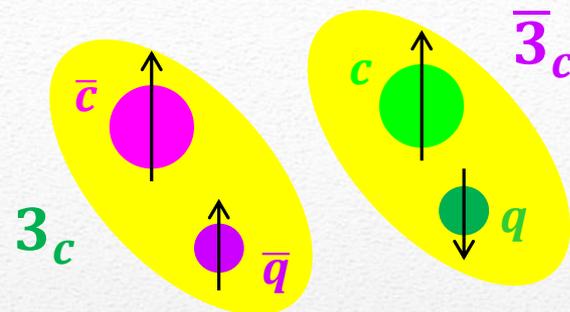

Faccini, Maiani, Piccinini, AP, Polosa, Riquer PRD87 111102

Maiani, Piccinini, Polosa, Riquer PRD89 114010

Spectrum according to **color-spin hamiltonian**  
(all the terms of the Breit-Fermi hamiltonian are absorbed into a constant diquark mass):

$$H = \sum_{dq} m_{dq} + 2 \sum_{i < j} \kappa_{ij} \vec{S}_i \cdot \vec{S}_j \frac{\lambda_i^a}{2} \frac{\lambda_j^a}{2}$$

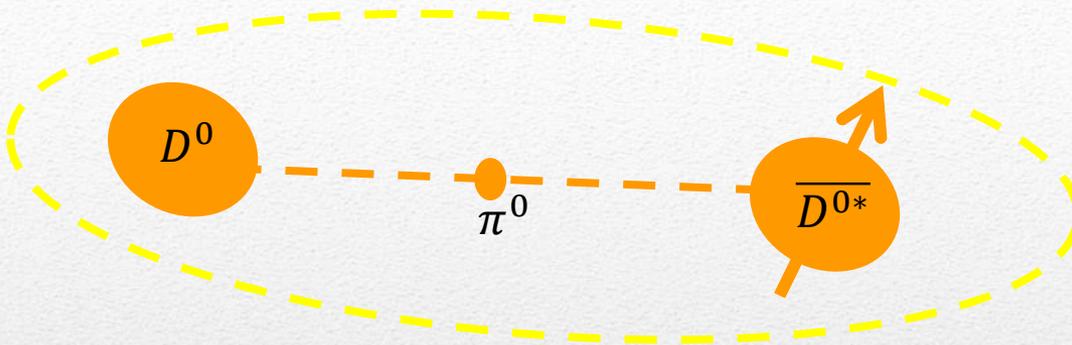

- Decay pattern mostly driven by **HQSS** ✓
- Fair understanding of existing spectrum ✓
- A full nonet for each level is expected ✗

New ansatz: the diquarks are compact objects spatially separated from each other,  
**only  $\kappa_{cq} \neq 0$**

Existing spectrum is fitted if  $\kappa_{cq} = 67$  MeV

# Other models: Molecule

Tornqvist, Z.Phys. C61, 525  
 Braaten and Kusunoki, PRD69 074005  
 Swanson, Phys.Rept. 429 243-305

$$\begin{aligned} X(3872) &\sim \bar{D}^0 D^{*0} \\ Z_c(3900) &\sim \bar{D}^0 D^{*+} \\ Z'_c(4020) &\sim \bar{D}^{*0} D^{*+} \\ Y(4260) &\sim \bar{D} D_1 \end{aligned}$$

A **deuteron-like meson pair**, the interaction is mediated by the exchange of light mesons

- Some model-independent relations (**Weinberg's theorem**) ✓
- Good description of **decay patterns** (mostly to constituents) and X(3872) **isospin violation** ✓
- States appear **close to thresholds** ✓ (but **Z(4430)** ✗)
- Lifetime of constituents has to be  $\gg 1/m_\pi$
- Binding energy varies from  $-70$  to  $-0.1$  MeV, or even **positive** (repulsive interaction) ✗
- **Unclear spectrum** (a state for each threshold?) – **depends on potential models** ✗

$$V_\pi(r) = \frac{g_{\pi N}^2}{3} (\vec{\tau}_1 \cdot \vec{\tau}_2) \left\{ [3(\vec{\sigma}_1 \cdot \hat{r})(\vec{\sigma}_2 \cdot \hat{r}) - (\vec{\sigma}_1 \cdot \vec{\sigma}_2)] \left( 1 + \frac{3}{(m_\pi r)^2} + \frac{3}{m_\pi r} \right) + (\vec{\sigma}_1 \cdot \vec{\sigma}_2) \right\} \frac{e^{-m_\pi r}}{r}$$

Needs regularization, cutoff dependence

# Weinberg theorem

Resonant scattering amplitude

$$f(ab \rightarrow c \rightarrow ab) = -\frac{1}{8\pi E_{CM}} g^2 \frac{1}{(p_a + p_b)^2 - m_c^2}$$

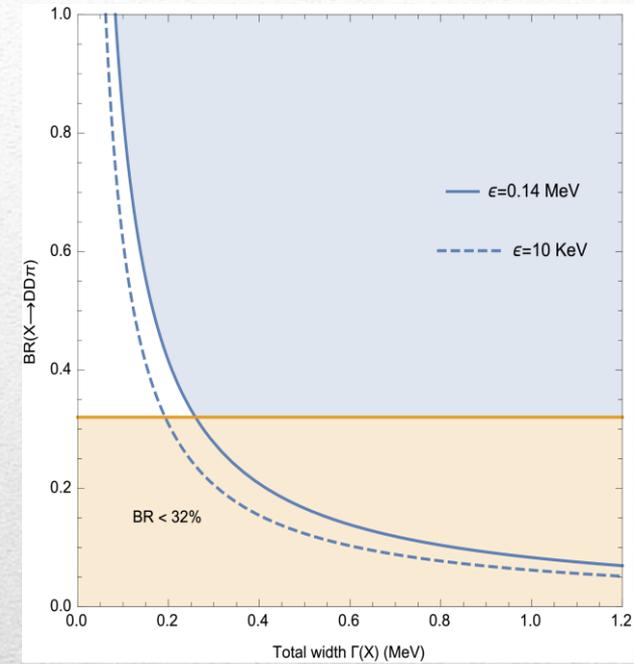

with  $m_c = m_a + m_b - B$ , and  $B, T \ll m_{a,b}$

$$f(ab \rightarrow c \rightarrow ab) = -\frac{1}{16\pi(m_a + m_b)^2} g^2 \frac{1}{B + T}$$

This has to be compared with the potential scattering for slow particles ( $kR \ll 1$ , being  $R \sim 1/m_\pi$  the range of interaction) in an attractive potential  $U$  with a superficial level at  $-B$

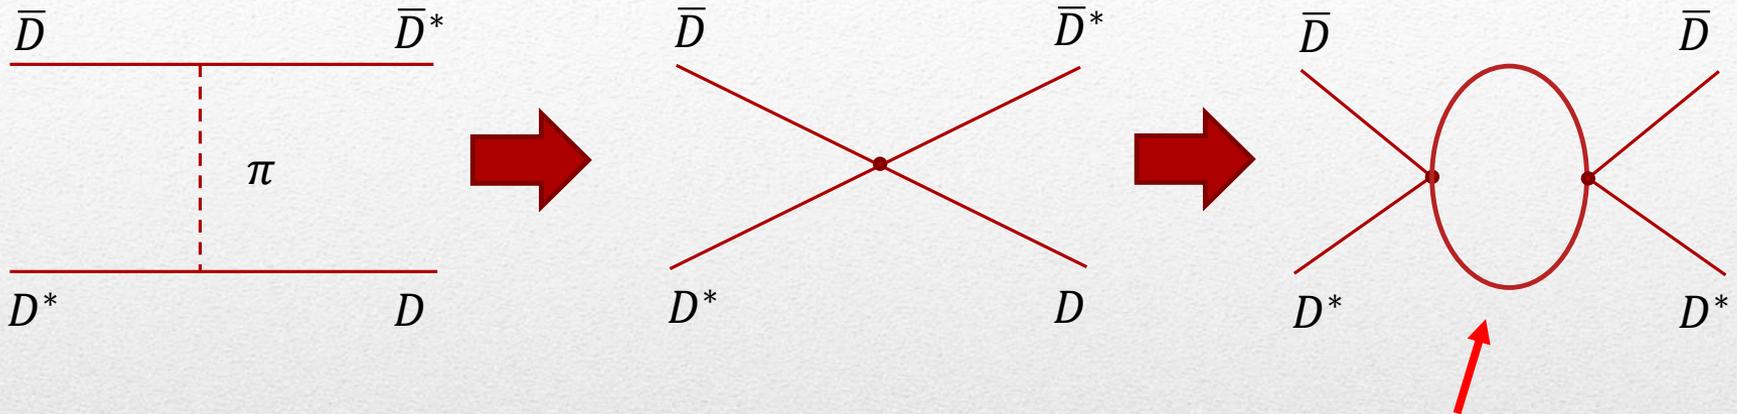

$$f(ab \rightarrow ab) = -\frac{1}{\sqrt{2\mu}} \frac{\sqrt{B} - i\sqrt{T}}{B + T}, \quad B = \frac{g^4}{512\pi^2} \frac{\mu^5}{(m_a m_b)^2}$$

This corresponds to the pure molecular interpretation of the  $X(3872)$

Weinberg, PR 130, 776  
Weinberg, PR 137, B672  
Polosa, PLB 746, 248

# Weinberg and amplitudes

This means that IF you can consider the pion exchange as a contact interaction, the amplitude is determined by the pole close to threshold

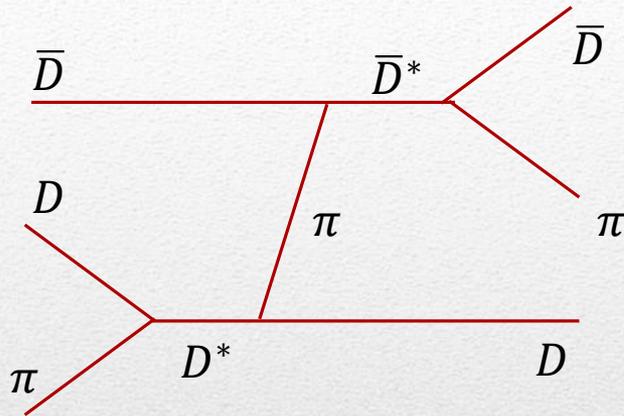

This loop is now divergent, I need to renormalize the integral I can put the pole where I want

Complex  $s$

# Weinberg and amplitudes

A. Jackura, AP et al., in progress

BUT the  $D^*$  actually decays into  $D\pi$  and the system is constrained by 3-body unitarity

The position of the pole can be calculated given a model for the simple pion exchange

The simplest model leads to a convergent dispersion relation, the pole position is determined  
One can check whether this purely molecular amplitude is consistent or not with data

Complex  $s$

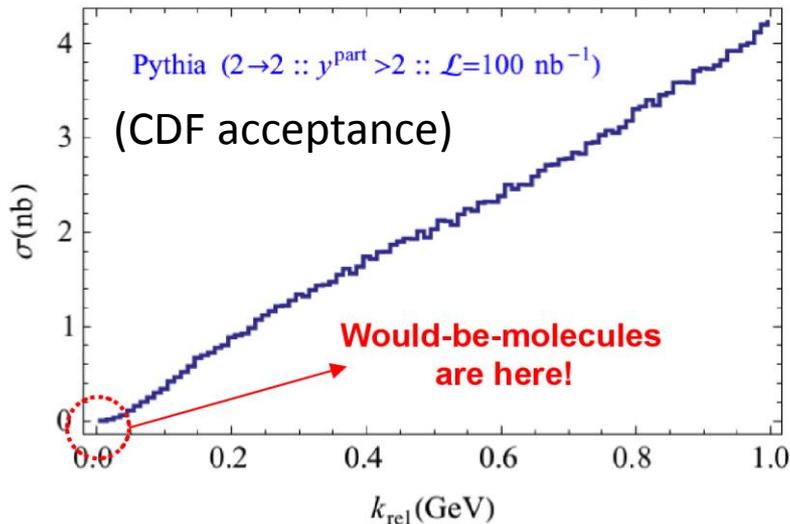

Short cut of real pion exchange

-----

pole?

# Prompt production of $X(3872)$

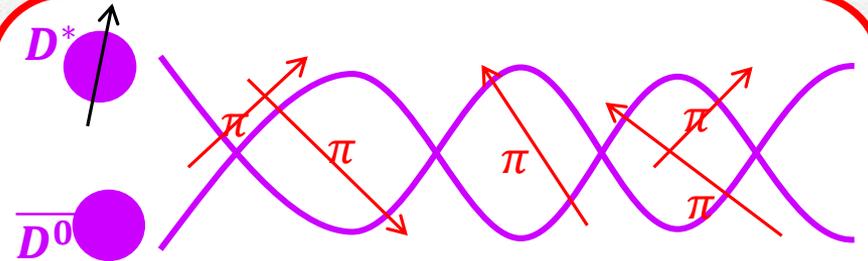

$X(3872)$  is the Queen of exotic resonances, the most popular interpretation is a  $D^0\bar{D}^{0*}$  molecule (bound state, pole in the 1<sup>st</sup> Riemann sheet?) but it is copiously promptly produced at hadron colliders

$$\sigma_{MC}(p\bar{p} \rightarrow DD^* | k < k_{max}) \approx 0.1 \text{ nb}$$

$$\sigma_{exp}(p\bar{p} \rightarrow X(3872)) \approx 30 - 70 \text{ nb!!!}$$

Bignamini *et al.* PRL103 (2009) 162001

A solution can be FSI (rescattering of  $DD^*$ ), which allow  $k_{max}$  to be as large as  $5m_\pi$ ,  
 $\sigma(p\bar{p} \rightarrow DD^* | k < k_{max}) \approx 230 \text{ nb}$

Artoisenet and Braaten, PRD81, 114018

However, the rescattering is flawed by the presence of pions that interfere with  $DD^*$  propagation. Estimating the effect of these pions increases  $\sigma$ , but not enough

Bignamini *et al.* PLB684, 228-230

Esposito, Piccinini, AP, Polosa, JMP 4, 1569

Guerrieri, Piccinini, AP, Polosa, PRD90, 034003

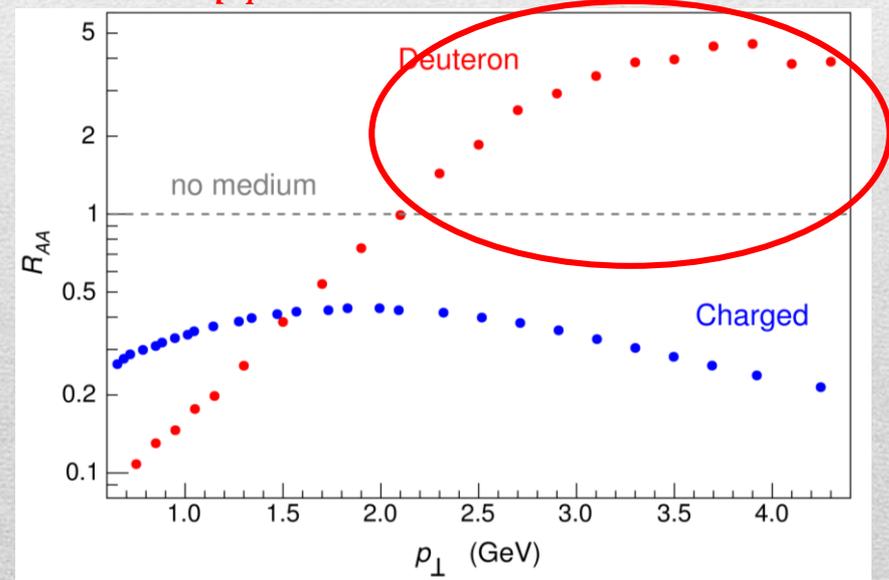

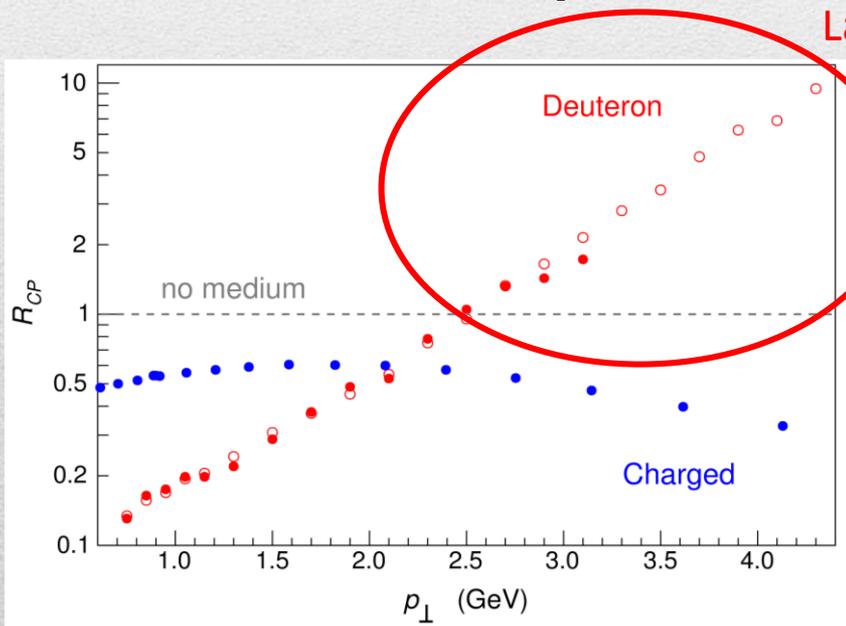

# Nuclear modification factors

What happens to molecules in heavy ion collisions?

We can use deuteron data to extract the values of the nuclear modification factors

$$R_{CP} = \frac{N_{coll}^P \left( \frac{dN}{dp_T} \right)_C}{N_{coll}^C \left( \frac{dN}{dp_T} \right)_P}$$

$$R_{AA} = \frac{\left( \frac{dN}{dp_T} \right)_{Pb-Pb}}{N_{coll} \left( \frac{dN}{dp_T} \right)_{pp}}$$

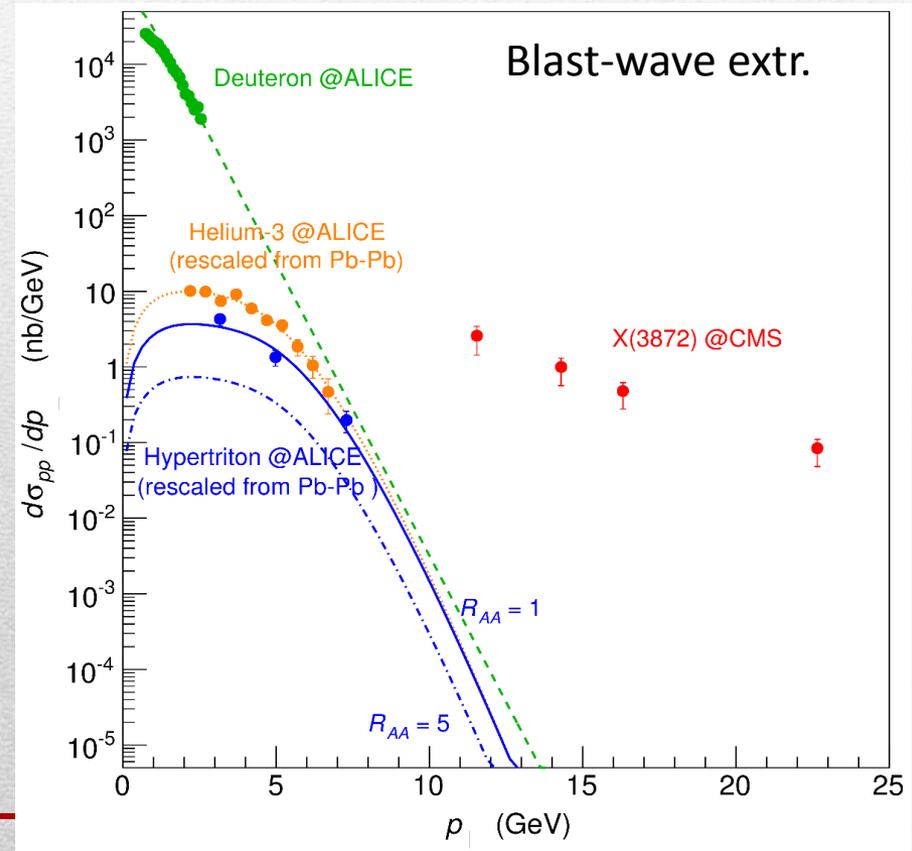

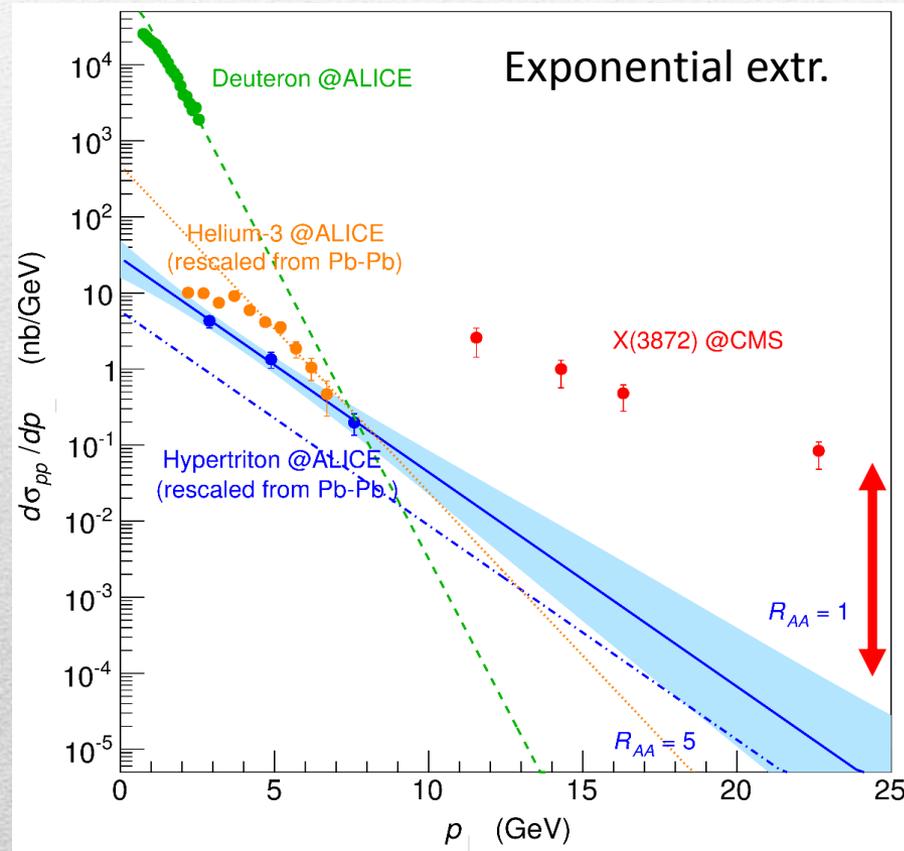

# Light nuclei at ALICE vs. $X(3872)$

Esposito, Guerrieri, Maiani, Piccinini, AP, Polosa, Riquer, PRD92, 034028

We assume a pure Glauber model ( $R_{AA} = 1$ ) and a value  $R_{AA} = 5$  to rescale Pb-Pb data to pp

The  $X(3872)$  is way larger than the extrapolated cross section

# Production of $Y(4260)$ and $P_c(4450)$

Given the new lineshape by BESIII, we need to rethink the binding energy of the  $Y(4260)$

J. Nys and AP, to appear

	Constituents	Bind. Energy	Bind. Mom.	Mediator
$X(3872)$	$\bar{D}^0 D^{*0}$	$\sim 100$ keV	$\sim 50$ MeV	$1\pi$ ( $\sim 300$ MeV)
$Y(4260)$	$\bar{D} D_1$	$\sim 70$ MeV	$\sim 400$ MeV	$2\pi$ ( $\sim 600$ MeV)
$P_c(4450)$	$\bar{D}^* \Sigma_c$	$\sim 10$ MeV	$\sim 150$ MeV	$1\pi$ ( $\sim 300$ MeV)

If the states are purely hadron molecule, all the properties depend on the position of the pole with respect to threshold – all the features are universal

What does the production of  $X(3872)$  implies for the other states?

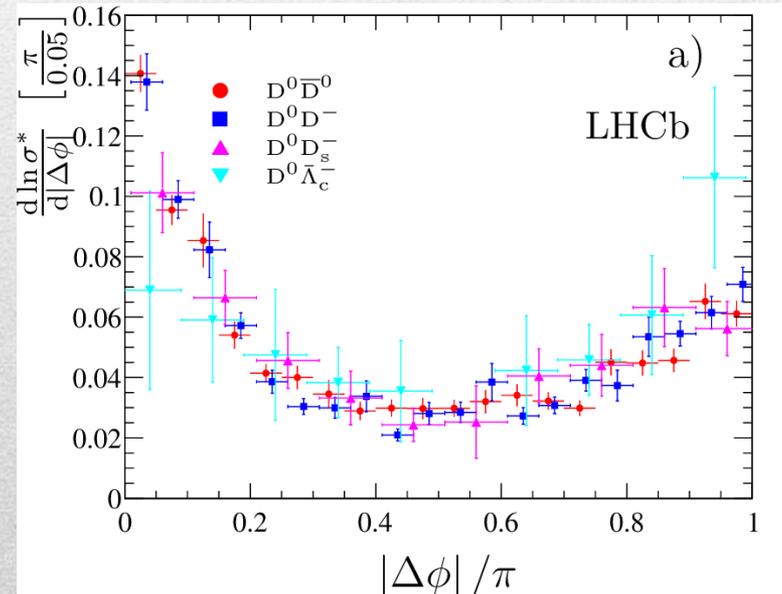

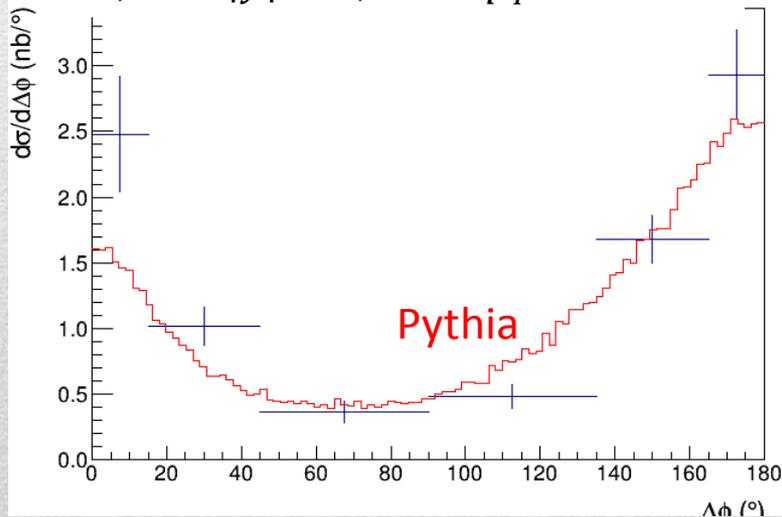

# Production of $Y(4260)$ and $P_c(4450)$

We can use Pythia to simulate the production of event, and calculate the relative production of  $Y(4260)$  and  $P_c(4450)$  with respect to the  $X(3872)$  J. Nys and AP, to appear

We tune our MC on charm pair production For baryons we can double check with LHCb data

CDF data,  $\sqrt{s} = 1.96$  TeV

$D^0, D^{*-}$ :  $|y| < 1, 5.5 < p_T < 20$  GeV

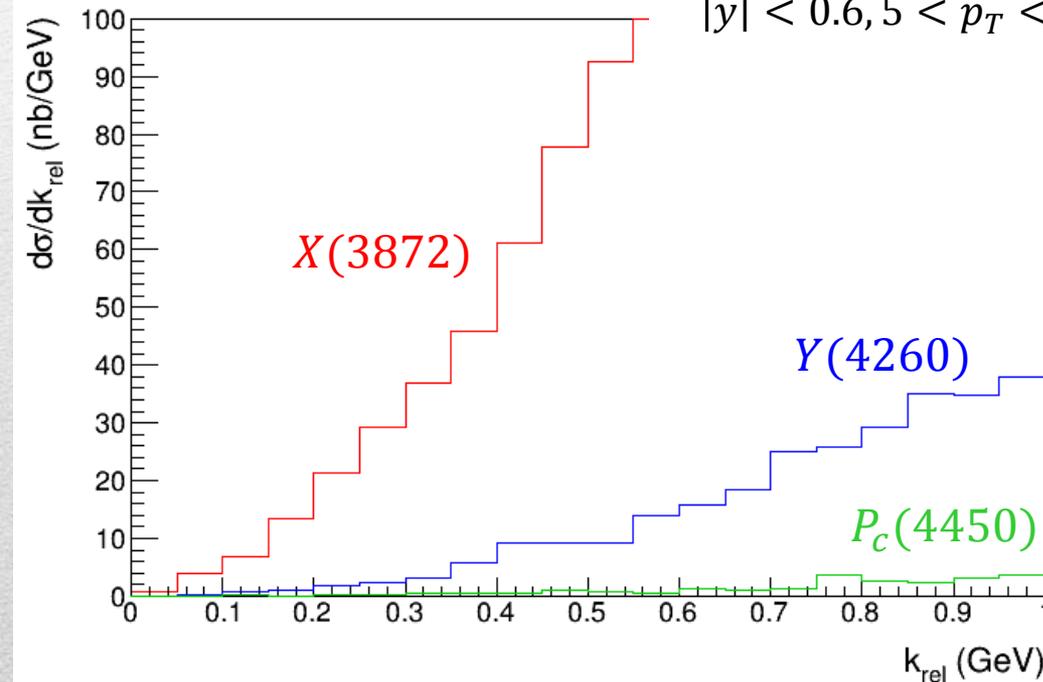

LHCb,  $\sqrt{s} = 7$  TeV, **JHEP 1206, 141**  
all:  $2 < y < 4, 3 < p_T < 12$  GeV

# Production of $Y(4260)$ and $P_c(4450)$

Naively, the fragmentation function of the  $D_1$  is 1/10 of the  $D^*$ ,  
but the cross section scales as  $k_{max}^3$

J. Nys and AP, to appear

Pythia  $p\bar{p}$ ,  $\sqrt{s} = 1.96$  TeV  
 $|y| < 0.6, 5 < p_T < 20$  GeV

	No FSI	With FSI
$Y(4260)/X$	23	0.75
$P_c(4450)/X$	1.0	0.01

The production of  $Y(4260)$   
is expected to be at worse comparable  
with the  $X(3872)$

# Conclusions & prospects

- The discovery of **exotic states** has challenged the well established Charmonium framework
- Experiments are (too) prolific! **Constant feedback on predictions**
- Thorough **amplitude analyses** might shed some light on the microscopic nature of the new states
- The implementation of **3-body unitarity** will be a major step to understand several of these phenomena
- **Some fantasy needed**, many phenomenological models introduced.
- **Nuclei observation at hadron colliders** can give an unexpected help in testing some phenomenological hypotheses for the XYZP states
- Search for exotic states in **prompt production** is a necessary step to improve our understanding of the sector

**Thank you**

# Dictionary – Quark model

$L$  = orbital angular momentum

$S$  = spin  $q + \bar{q}$

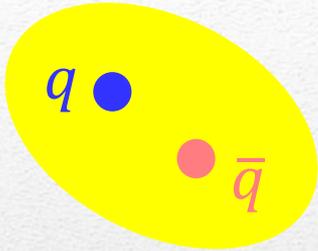

$J$  = total angular momentum  
= exp. measured spin

$I$  = isospin = 0 for quarkonia

$$L - S \leq J \leq L + S$$

$$P = (-1)^{L+1}, C = (-1)^{L+S}$$

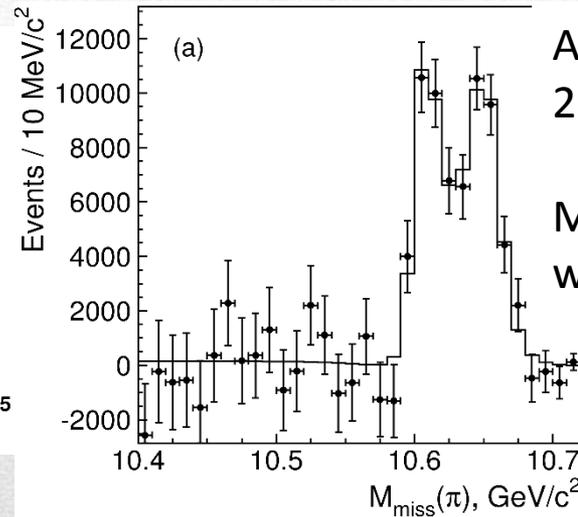

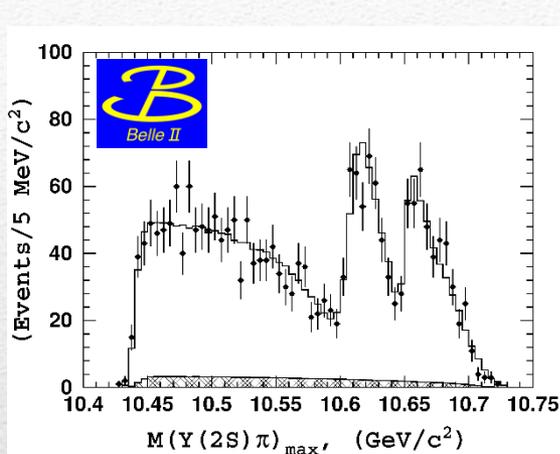

$$G = (-1)^{L+S+I}$$

$J^{PC}$	$L$	$S$	Charmonium ( $c\bar{c}$ )	Bottomonium ( $b\bar{b}$ )
$0^{-+}$	0 ( $S$ -wave)	0	$\eta_c(nS)$	$\eta_b(nS)$
$1^{--}$		1	$\psi(nS)$	$\Upsilon(nS)$
$1^{+-}$	1 ( $P$ -wave)	0	$h_c(nP)$	$h_b(nP)$
$0^{++}$		1	$\chi_{c0}(nP)$	$\chi_{b0}(nP)$
$1^{++}$		1	$\chi_{c1}(nP)$	$\chi_{b1}(nP)$
$2^{++}$		1	$\chi_{c2}(nP)$	$\chi_{b2}(nP)$

But  $J/\psi = \psi(1S)$ ,  $\psi' = \psi(2S)$

# Charged $Z$ states: $Z_b(10610)$ , $Z'_b(10650)$

Anomalous dipion width in  $\Upsilon(5S)$ ,  
2 orders of magnitude larger than  $\Upsilon(nS)$

Moreover, observed  $\Upsilon(5S) \rightarrow h_b(nP)\pi\pi$   
which violates HQSS

2 twin resonances!

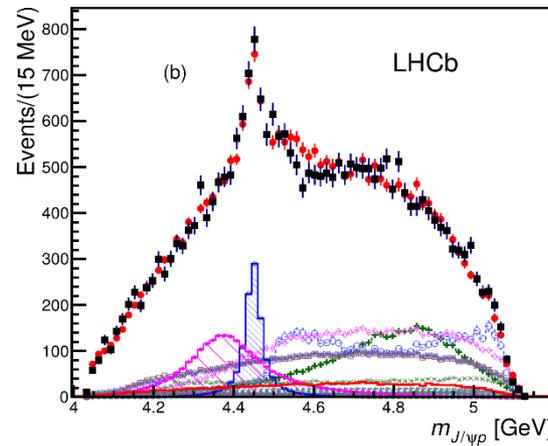

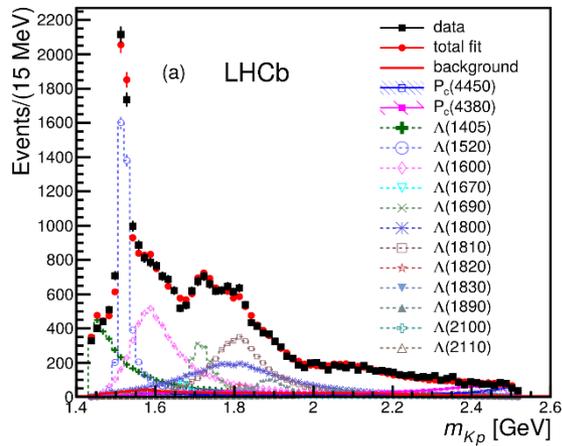

$\Upsilon(5S) \rightarrow Z_b(10610)^+\pi^- \rightarrow \Upsilon(nS)\pi^+\pi^-$ ,  $h_b(nP)\pi^+\pi^-$   
and  $\rightarrow (BB^*)^+\pi^-$

$M = 10607.2 \pm 2.0$  MeV,  $\Gamma = 18.4 \pm 2.4$  MeV

$\Upsilon(5S) \rightarrow Z'_b(10650)^+\pi^- \rightarrow \Upsilon(nS)\pi^+\pi^-$ ,  $h_b(nP)\pi^+\pi^-$   
and  $\rightarrow \bar{B}^{*0}B^{*+}\pi^-$

$M = 10652.2 \pm 1.5$  MeV,  $\Gamma = 11.5 \pm 2.2$  MeV

# Pentaquarks!

LHCb, PRL 115, 072001  
LHCb, PRL 117, 082003

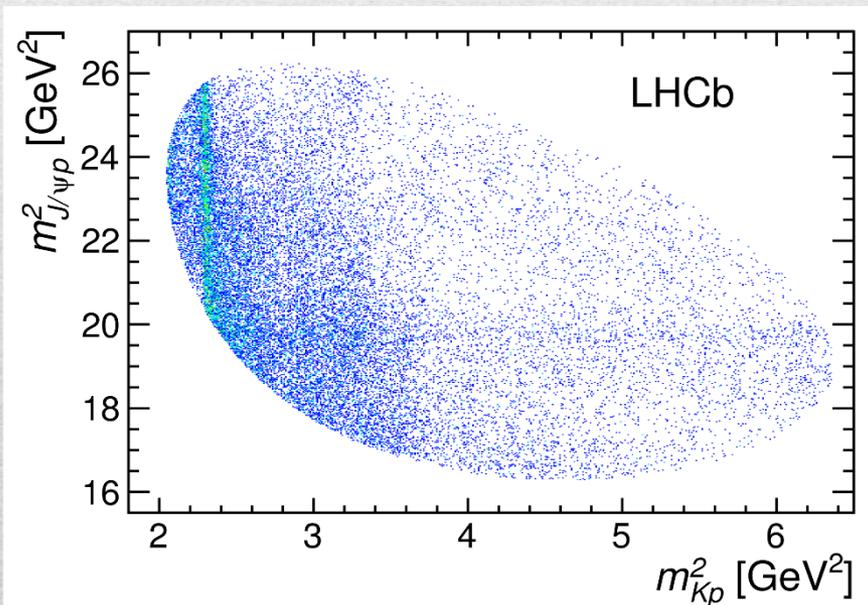

Two states seen in  $\Lambda_b \rightarrow (J/\psi p) K^-$ ,  
evidence in  $\Lambda_b \rightarrow (J/\psi p) \pi^-$

$$M_1 = 4380 \pm 8 \pm 29 \text{ MeV}$$

$$\Gamma_1 = 205 \pm 18 \pm 86 \text{ MeV}$$

$$M_2 = 4449.8 \pm 1.7 \pm 2.5 \text{ MeV}$$

$$\Gamma_2 = 39 \pm 5 \pm 19 \text{ MeV}$$

Quantum numbers

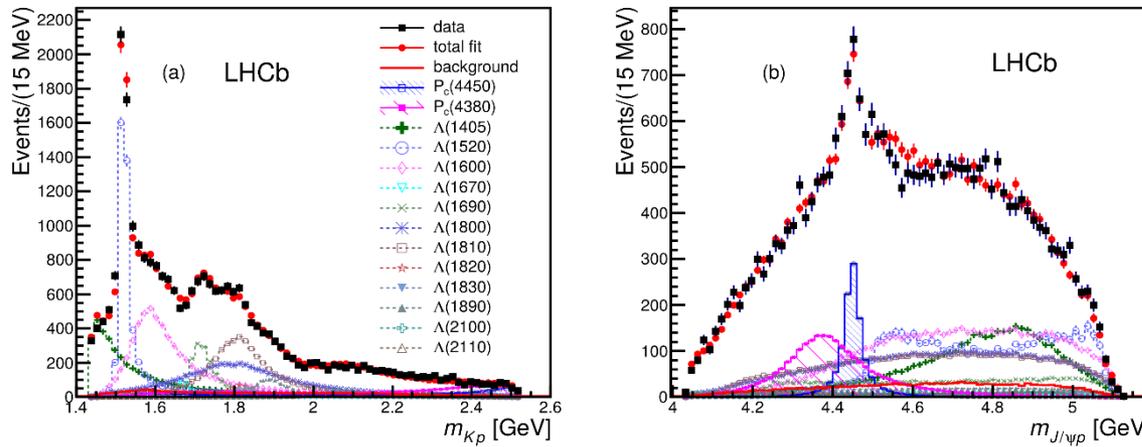

$$J^P = \left( \frac{3^-}{2}, \frac{5^+}{2} \right) \text{ or } \left( \frac{3^+}{2}, \frac{5^-}{2} \right) \text{ or } \left( \frac{5^+}{2}, \frac{3^-}{2} \right)$$

Opposite parities needed for the  
interference to correctly describe angular  
distributions, **low mass region**  
**contaminated by  $\Lambda^*$  (model dependence?)**

No obvious threshold nearby

# Pentaquarks!

LHCb, PRL 115, 072001  
LHCb, PRL 117, 082003

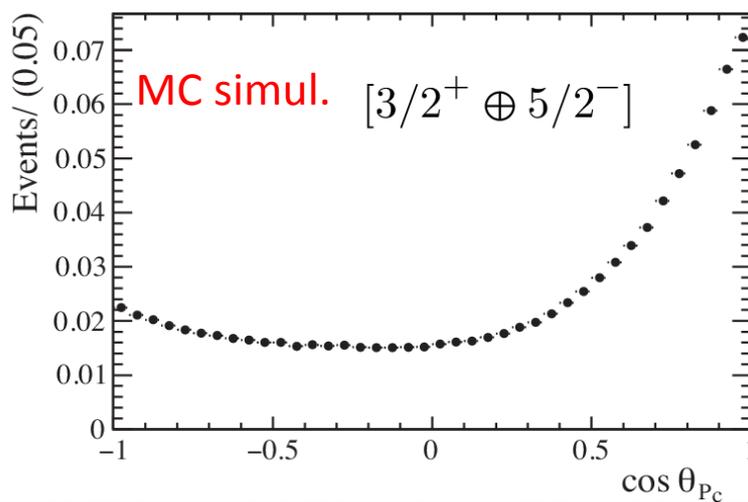

Two states seen in  $\Lambda_b \rightarrow (J/\psi p) K^-$ ,  
evidence in  $\Lambda_b \rightarrow (J/\psi p) \pi^-$

 $\Gamma_1 = 205 \pm 18 \pm 86 \text{ MeV}$   
 $M_2 = 4449.8 \pm 1.7 \pm 2.5 \text{ MeV}$   
 $\Gamma_2 = 39 \pm 5 \pm 19 \text{ MeV}$

Quantum numbers

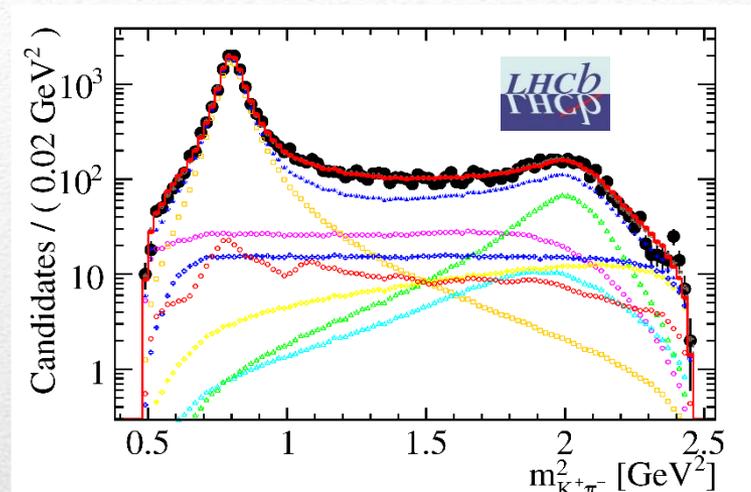

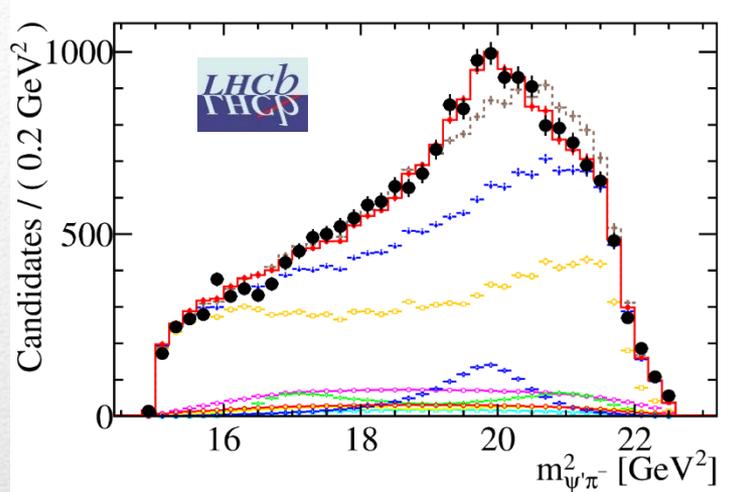

$$J^P = \left( \frac{3^-}{2}, \frac{5^+}{2} \right) \text{ or } \left( \frac{3^+}{2}, \frac{5^-}{2} \right) \text{ or } \left( \frac{5^+}{2}, \frac{3^-}{2} \right)$$

Opposite parities needed for the  
interference to correctly describe angular  
distributions, **low mass region**  
**contaminated by  $\Lambda^*$  (model dependence?)**

No obvious threshold nearby

# Charged Z states: Z(4430)

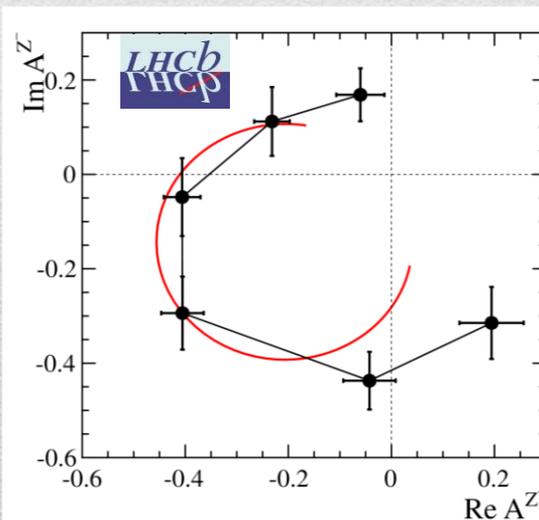

$$Z(4430)^+ \rightarrow \psi(2S) \pi^+$$

$$I^G J^{PC} = 1^+ 1^{+-}$$

$$M = 4475 \pm 7_{-25}^{+15} \text{ MeV}$$

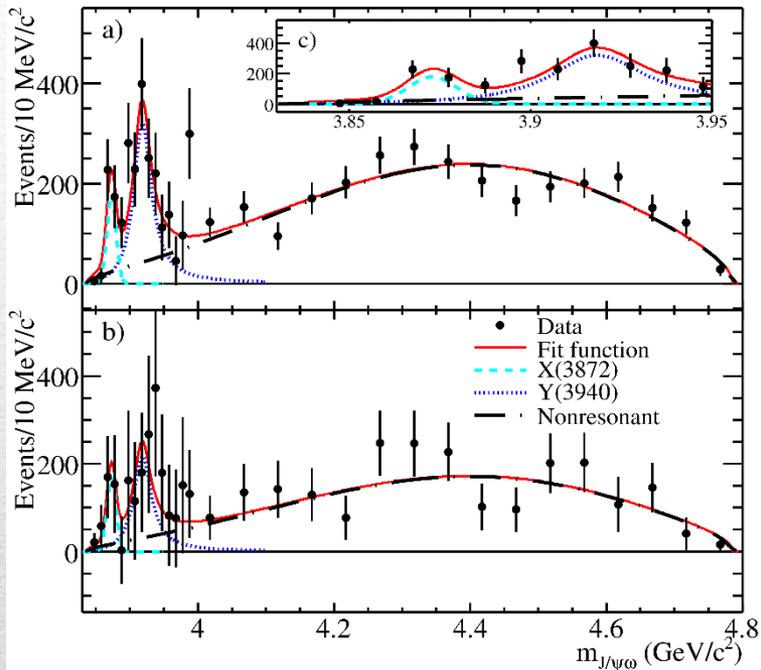

$$\Gamma = 172 \pm 13_{-34}^{+37} \text{ MeV}$$

Far from open charm thresholds

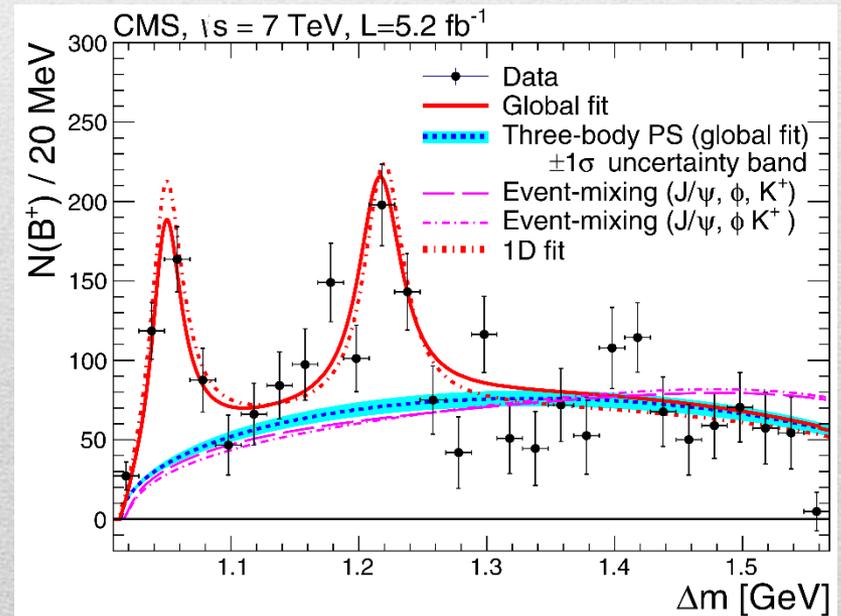

If the amplitude is a free complex number, in each bin of  $m_{\psi' \pi^-}^2$ , the resonant behaviour appears as well

# Other beasts

One/two peaks seen in  $B \rightarrow XK \rightarrow J/\psi \phi K$ , close to threshold

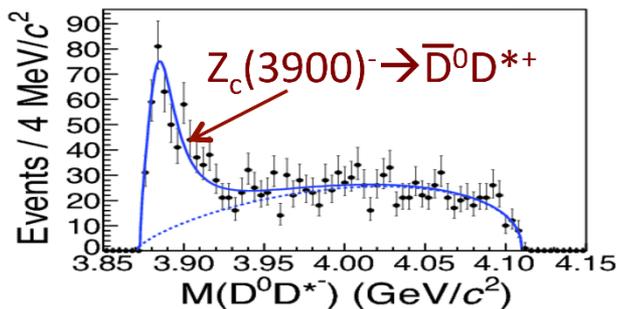

$X(3915)$ , seen in  $B \rightarrow XK \rightarrow J/\psi \omega$   
 and  $\gamma\gamma \rightarrow X \rightarrow J/\psi \omega$   
 $J^{PC} = 0^{++}$ , candidate for  $\chi_{c0}(2P)$   
 But  $X(3915) \not\rightarrow D\bar{D}$  as expected,  
 and the hyperfine splitting  
 $M(2^{++}) - M(0^{++})$  too small

# $Y(4260) \rightarrow \bar{D}D_1?$

$e^+e^- \rightarrow Y(4260) \rightarrow \pi^- \bar{D}^0 D^{*+}$

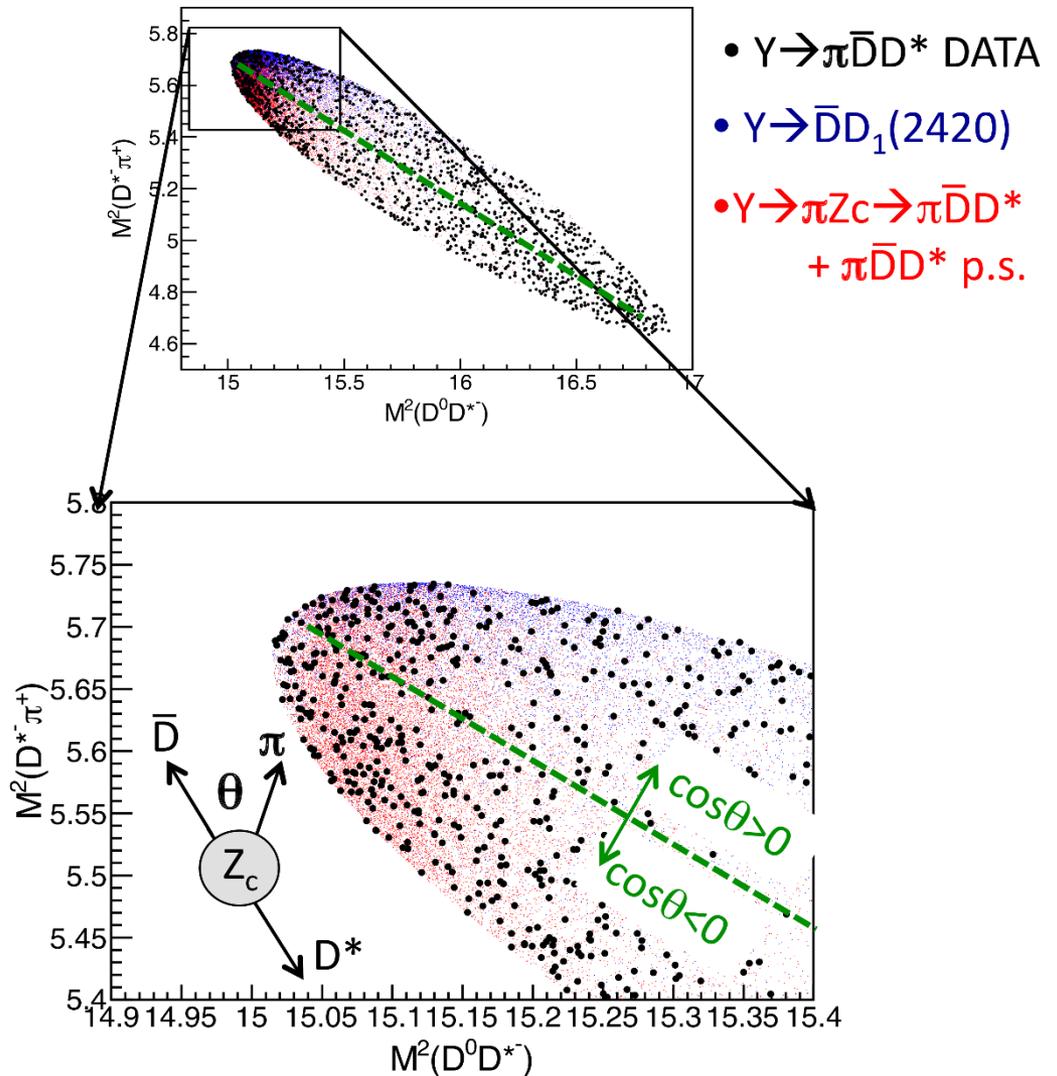

BESIII PRL 112, 022001

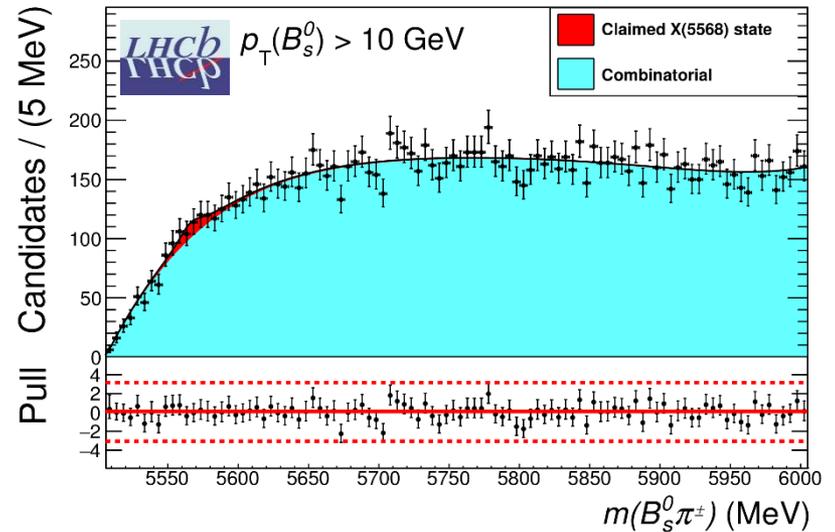

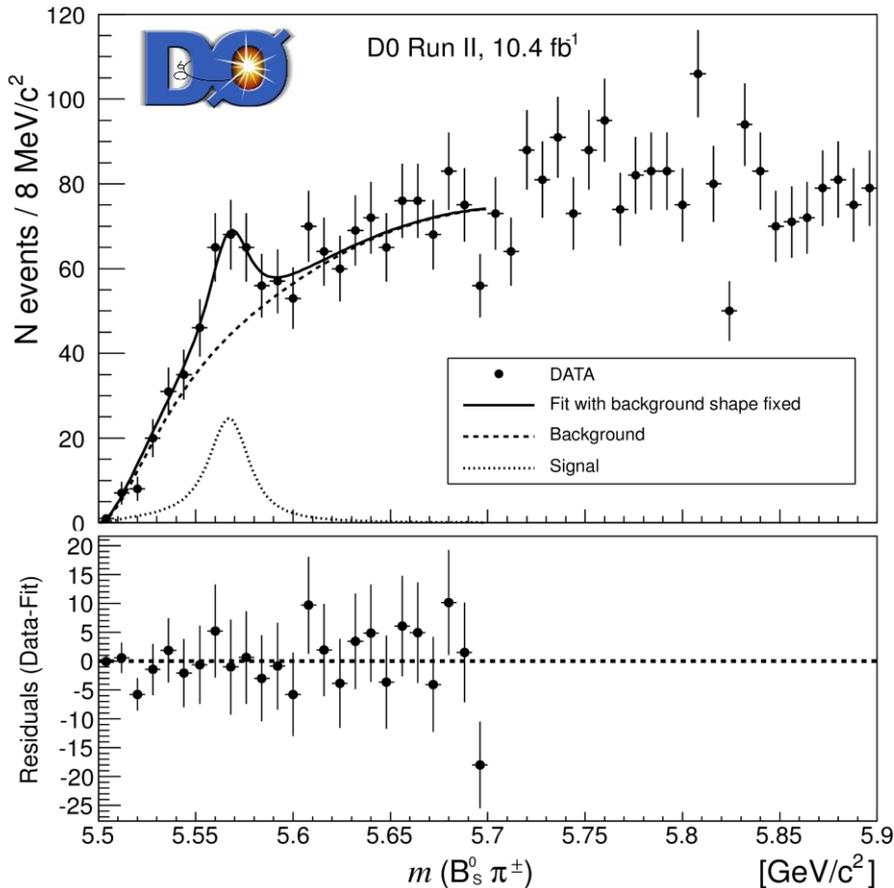

$$\mathcal{A} = \frac{N_{|\cos\theta|>0.5} - N_{|\cos\theta|<0.5}}{N_{|\cos\theta|>0.5} + N_{|\cos\theta|<0.5}}$$

	DD <sub>1</sub> MC	Z <sub>c</sub> +ps MC	data
$\mathcal{A}$	$0.43 \pm 0.04$	$0.02 \pm 0.02$	$0.12 \pm 0.06$

Not a lot of room for  $\bar{D}D_1(2410)$

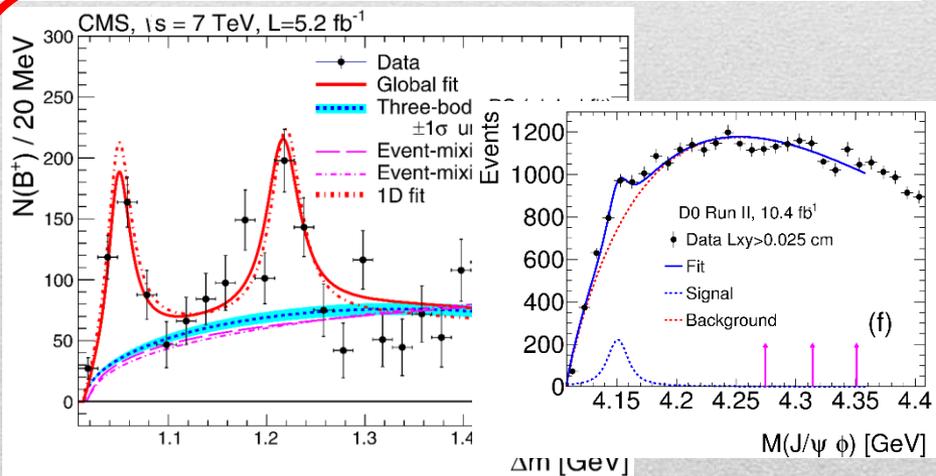

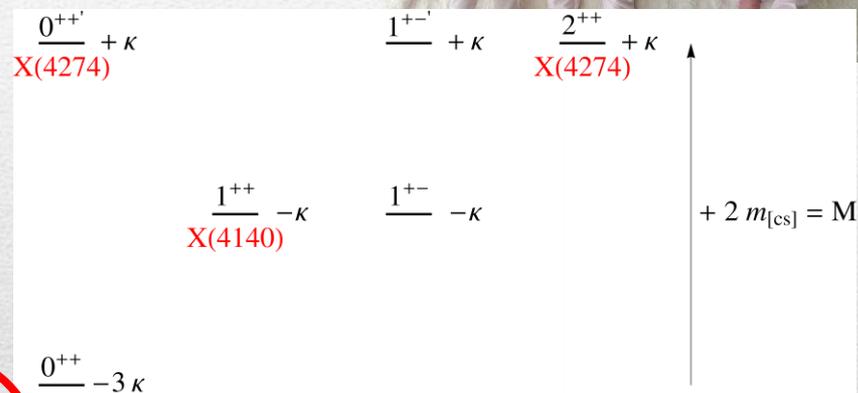

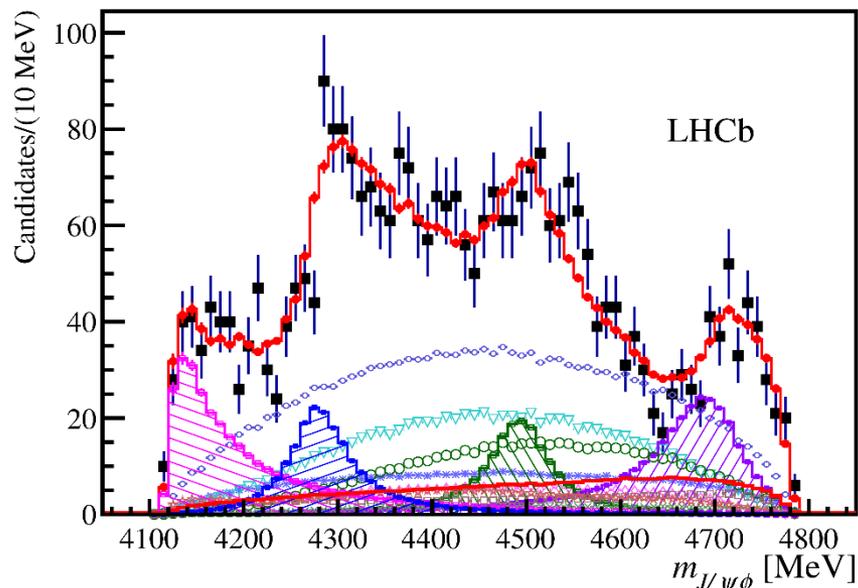

# Flavored X(5568)

- A **flavored state** seen in  $B_s^0 \pi$  invariant mass by D0 (both  $B_s^0 \rightarrow J/\psi \phi$  and  $\rightarrow D_s \mu \nu$ ),
- **not conformed** by LHCb or CMS
- (different kinematics? Compare differential distributions)

Controversy to be solved

# Tetraquark: the $c\bar{c}s\bar{s}$ states

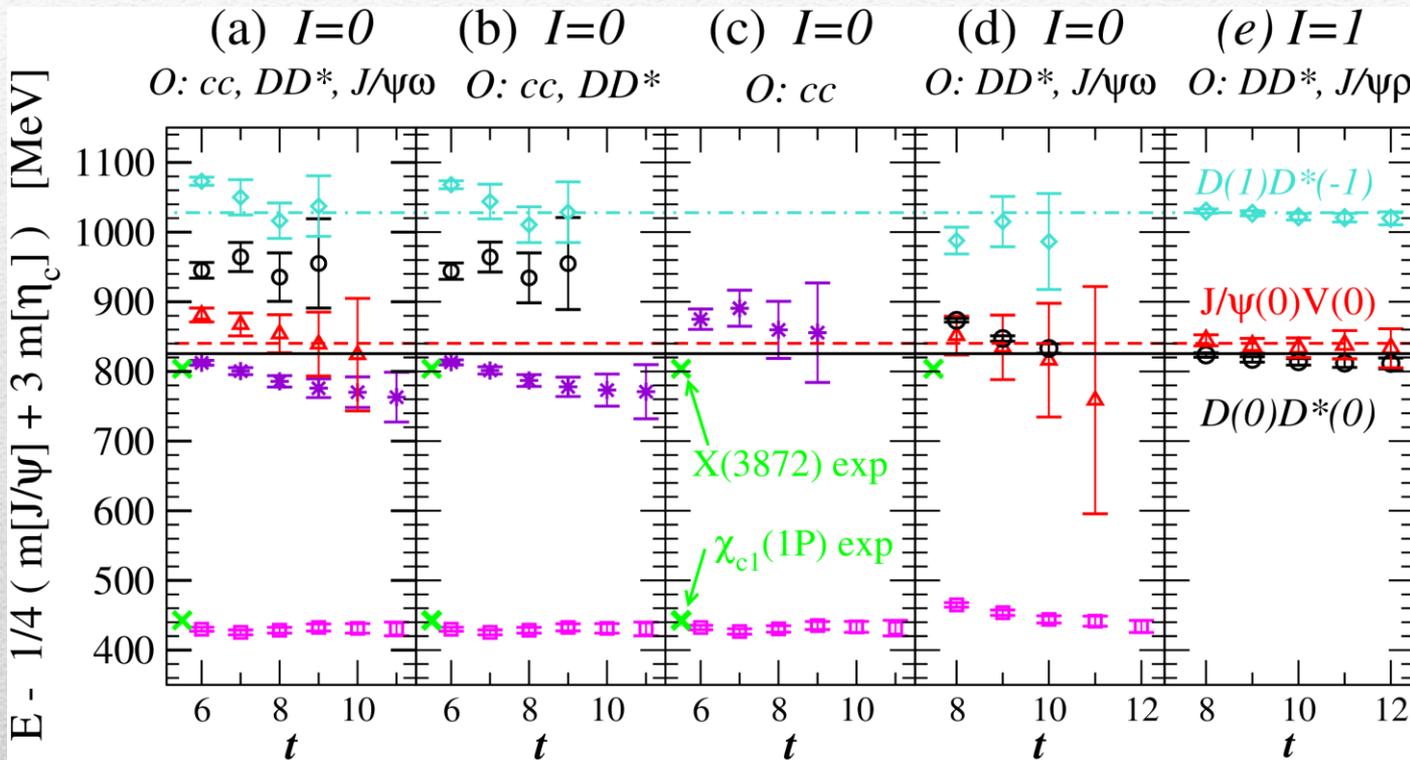

Good description of the spectrum **but** one has to assume the axial assignment for the  $X(4274)$  to be incorrect (two unresolved states with  $0^{++}$  and  $2^{++}$ )

Maiani, Polosa and Riquer, PRD 94, 054026

Much narrower than LHCb! Look for prompt!

# $X(3872)$ on the lattice

There is only evidence (?) for the  $X(3872)$  in the  $I^G J^{PC} = 0^+ 1^{++}$  channel

Caveats:

- Small lattices, large artifacts
- Three body dynamics may play a role
- Interpretation of the overlap coefficients is questionable

Status of other XYZ on the lattice is even less clear

S. Prelovsek, L. Leskovec, PRL111, 192001

# Multiscale system

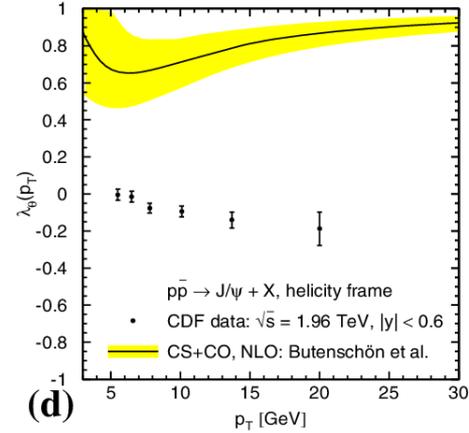

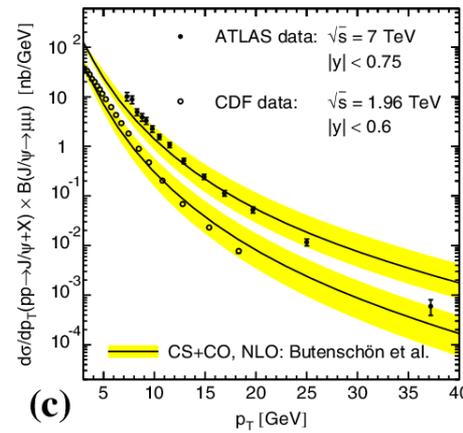

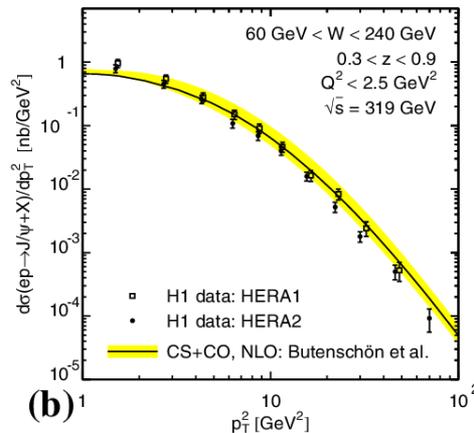

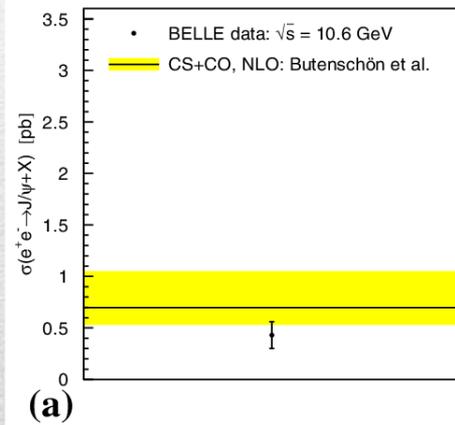

Systematically integrate out the heavy scale,  
 $m_Q \gg \Lambda_{QCD}$

$$m_Q \gg m_Q v \gg m_Q v^2$$

Full QCD  $\longrightarrow$  NRQCD  $\longrightarrow$  pNRQCD

$$m_b \sim 5 \text{ GeV}, m_c \sim 1.5 \text{ GeV}$$

$$v_b^2 \sim 0.1, v_c^2 \sim 0.3$$

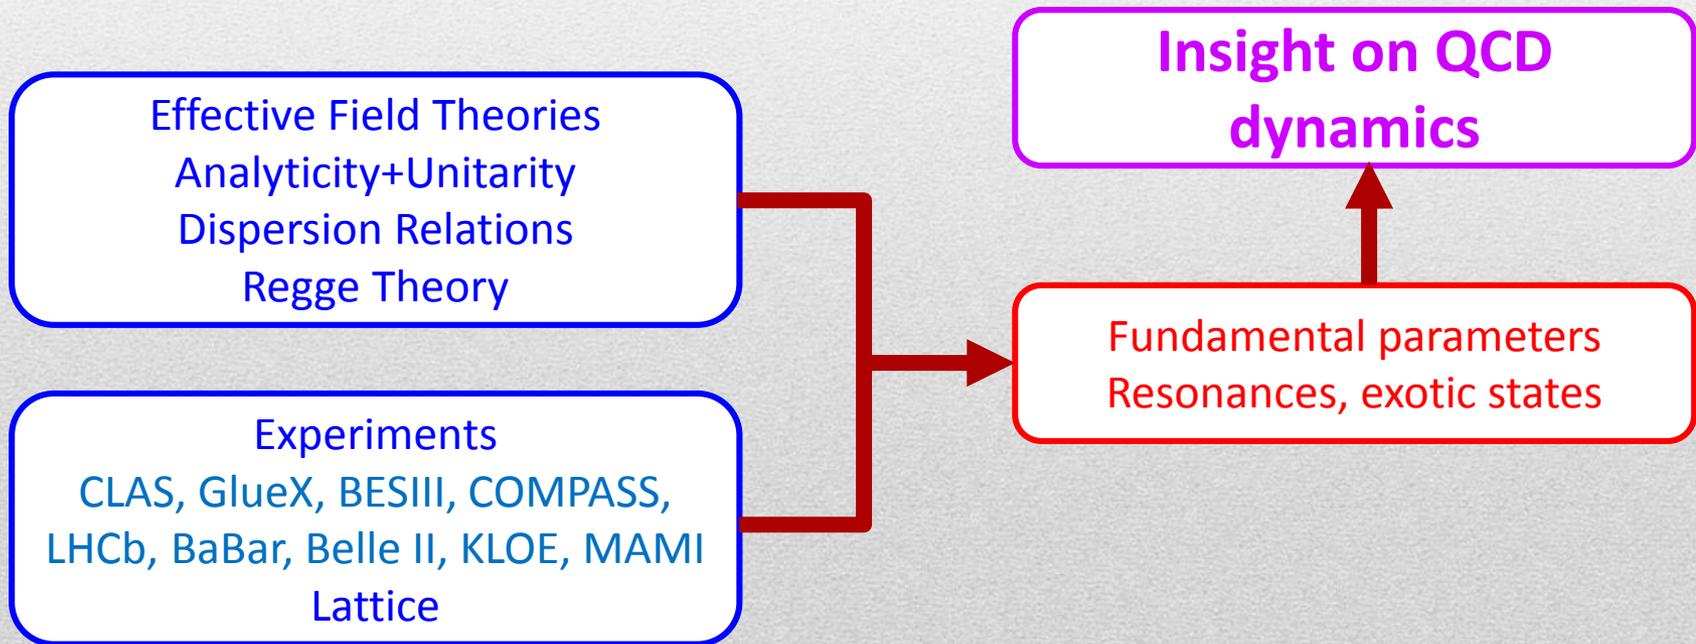

Factorization (to be proved)  
of universal LDMEs

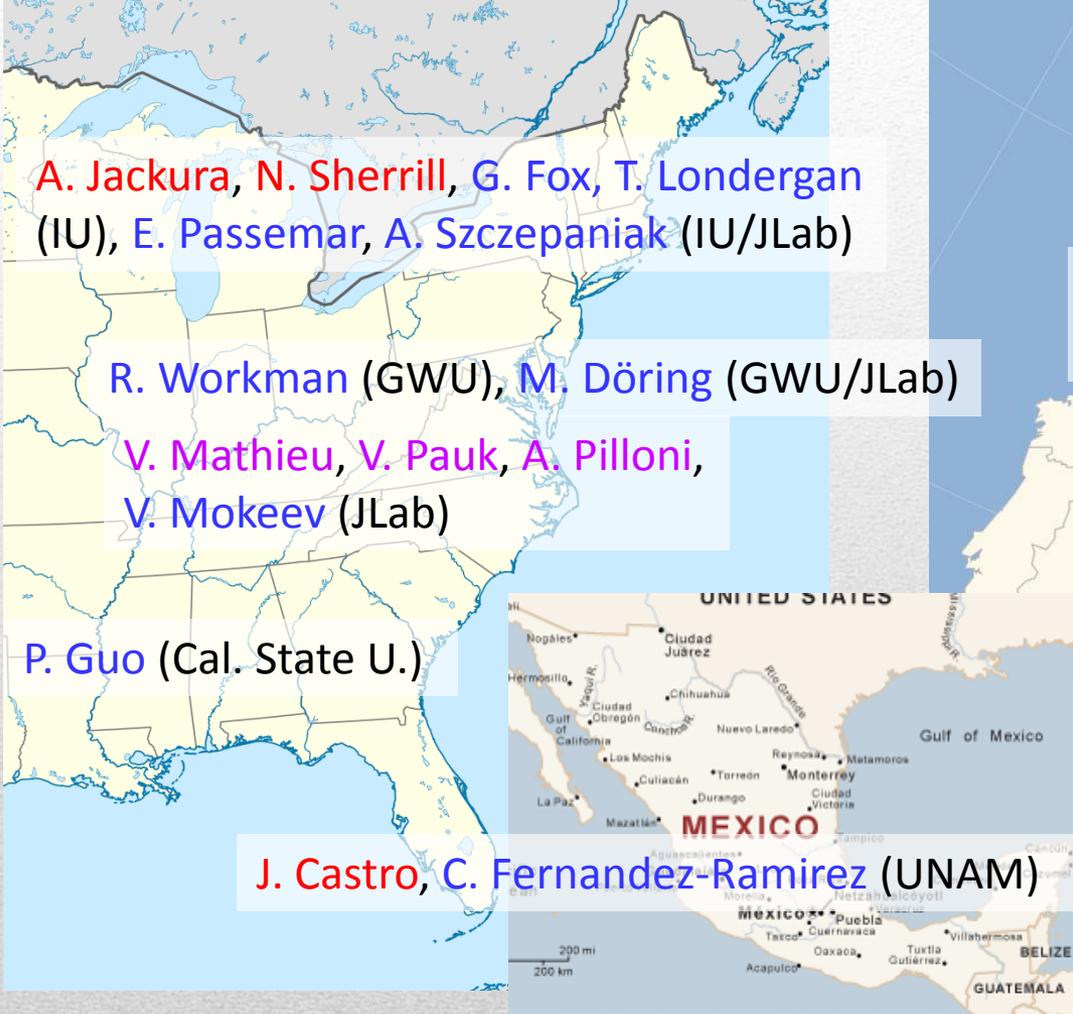

Good description of many production channels,  
some known puzzles (polarizations)

# Joint Physics Analysis Center

- **Joint effort** between **theorists** and **experimentalists** to work together to make the best use of the next generation of very precise data taken at JLab and in the world
- Created in 2013 by JLab & IU agreement
- It is engaged in **education** of further generations of hadron physics practitioners

### Formalism

The pion-nucleon scattering is a function of 2 variables. The first is the beam momentum in the laboratory frame  $p_{lab}$  (in GeV) or the total energy squared  $s = W^2$  (in  $\text{GeV}^2$ ). The second is the cosine of

### Resources

- **Publications:** [Mat15a] and [Wor12a]
- **SAID partial waves:** compressed zip file
- **C/C++:** C/C++ file
- **Input file:** param.txt
- **Output files:** output0.txt, output1.txt, SigTot.txt, Observables0.txt, Observables1.txt
- **Contact person:** Vincent Mathieu
- **Last update:** June 2016

The SAID partial waves are in the format provided online on the SAID webpage :

$p_{lab}$     $\delta$     $\epsilon(\delta)$     $1 - \eta^2$     $\epsilon(1 - \eta^2)$    Re PW   Im PW   SGT   SGR

$\delta$  and  $\eta$  are the phase-shift and the inelasticity.  $\epsilon(x)$  is the error on  $x$ . SGT is the total cross section and SGR is the total reaction cross section.

Format of the input and output files: [show/hide]  
Description of the C/C++ code: [show/hide]

### Simulation

Range of the running variable:

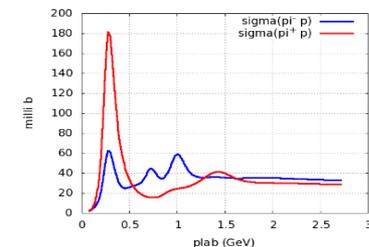

$s$ in $\text{GeV}^2$ (min max step)	1,2	:	6	:	0,01	:
$p_{lab}$ in GeV (min max step)	0,1	:	4	:	0,01	:
$\nu$ in GeV (min max step)	0,3	:	4	:	0,01	:
$t$ in $\text{GeV}^2$ (min max step)	-1	:	0	:	0,01	:

The fixed variable:

$t$  in  $\text{GeV}^2$

$p_{lab}$  in GeV

### Results

# Strategy

AP *et al.* (JPAC), arXiv:1612.06490

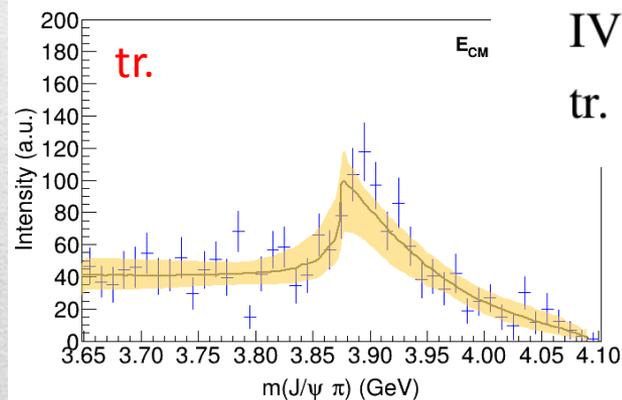

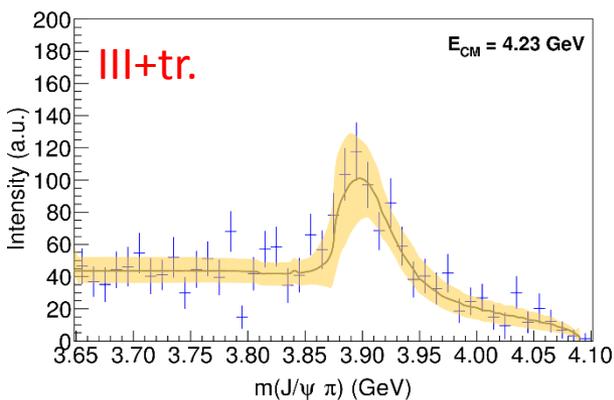

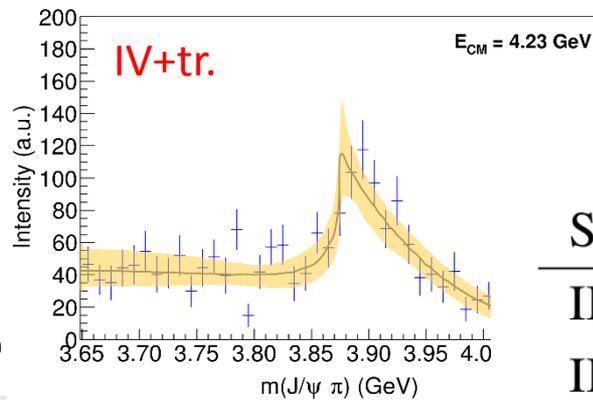

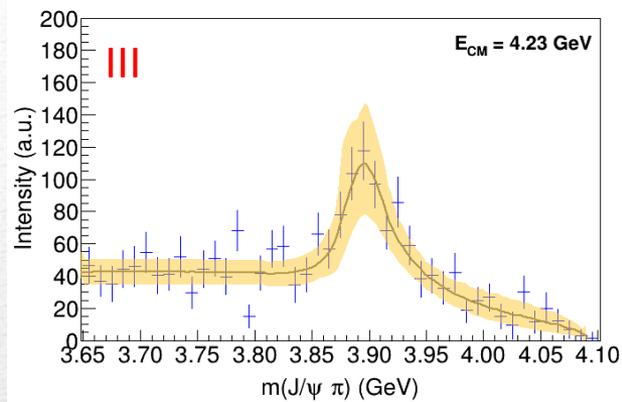

- We fit the following **invariant mass distributions**:
  - BESIII PRL110, 252001  $J/\psi \pi^+, J/\psi \pi^-, \pi^+ \pi^-$  at  $E_{CM} = 4.26$  GeV
  - BESIII PRL110, 252001  $J/\psi \pi^0$  at  $E_{CM} = 4.23, 4.26, 4.36$  GeV
  - BESIII PRD92, 092006  $\overline{D^0} D^{*+}, \overline{D^{*0}} D^+$  (double tag) at  $E_{CM} = 4.23, 4.26$  GeV
  - BESIII PRL115, 222002  $\overline{D^0} D^{*0}, \overline{D^{*0}} D^0$  at  $E_{CM} = 4.23, 4.26$  GeV
  - ~~BESIII PRL112, 022001  $\overline{D^0} D^{*+}, \overline{D^{*0}} D^+$  (single tag) at  $E_{CM} = 4.26$  GeV~~
  - ~~Belle PRL110, 252002  $J/\psi \pi^\pm$  at  $E_{CM} = 4.26$  GeV~~
  - ~~CLEO-c data PLB727, 366  $J/\psi \pi^\pm, J/\psi \pi^0$  at  $E_{CM} = 4.17$  GeV~~
- Published data are not efficiency/acceptance corrected,  
→ we are **not able to give the absolute normalization** of the amplitudes
- No given dependence on  $E_{CM}$  is assumed – the couplings at different  $E_{CM}$  are independent parameters

# Strategy

AP *et al.* (JPAC), arXiv:1612.06490

- **Reducible** (incoherent) **backgrounds are pretty flat** and do not influence the analysis, except the peaking background in  $\overline{D^0}D^{*0}, \overline{D^{*0}}D^0$  (subtracted)
- Some information about **angular distributions** has been published, but it's **not constraining** enough → we do not include in the fit
- Because of that, **we approximate all the particles to be scalar** – this affects the value of couplings, which are not normalized anyway – but not the position of singularities. This also limits the number of free parameters

# Fit summary

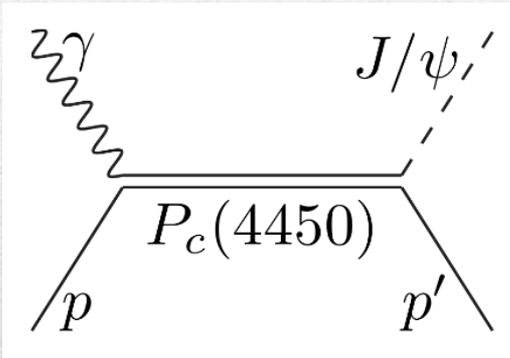

Scenario	$\chi^2$	DOF	$\chi^2/\text{DOF}$
III	644	532	1.21
III+tr.	642	532	1.21
IV+tr.	666	532	1.25
tr.	695	532	1.31

Naive loglikelihood ratio test give a  $\sim 4\sigma$  significance of the scenario III+tr. over IV+tr., looking at plots it looks too much – better using some more solid test

# $P_c$ photoproduction

To exclude any rescattering mechanism, we propose to search the  $P_c(4450)$  state in **photoproduction**.

Vector meson dominance relates the radiative width to the hadronic width

$$\langle \lambda_\psi \lambda_{p'} | T_r | \lambda_\gamma \lambda_p \rangle = \frac{\langle \lambda_\psi \lambda_{p'} | T_{\text{dec}} | \lambda_R \rangle \langle \lambda_R | T_{\text{em}}^\dagger | \lambda_\gamma \lambda_p \rangle}{M_r^2 - W^2 - i\Gamma_r M_r}$$

Hadronic vertex
EM vertex

## Hadronic part

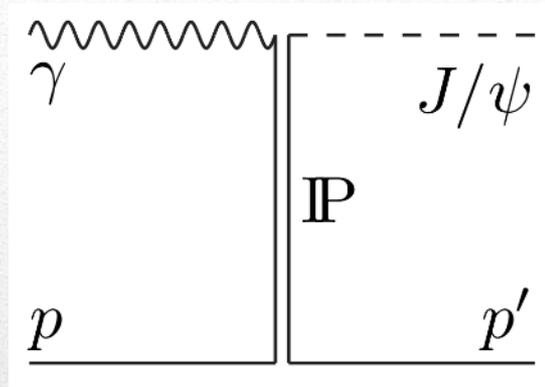

- 3 independent helicity couplings,  $\rightarrow$  approx. equal,  $g_{\lambda_\psi, \lambda_{p'}} \sim g$
- $g$  extracted from total width and (unknown) branching ratio

$$\Gamma_\gamma = 4\pi\alpha \Gamma_{\psi p} \left( \frac{f_\psi}{M_\psi} \right)^2 \left( \frac{\bar{p}_i}{\bar{p}_f} \right)^{2\ell+1} \times \frac{4}{6}$$

Hiller Blin, AP *et al.* (JPAC), PRD94, 034002

# Background parameterization

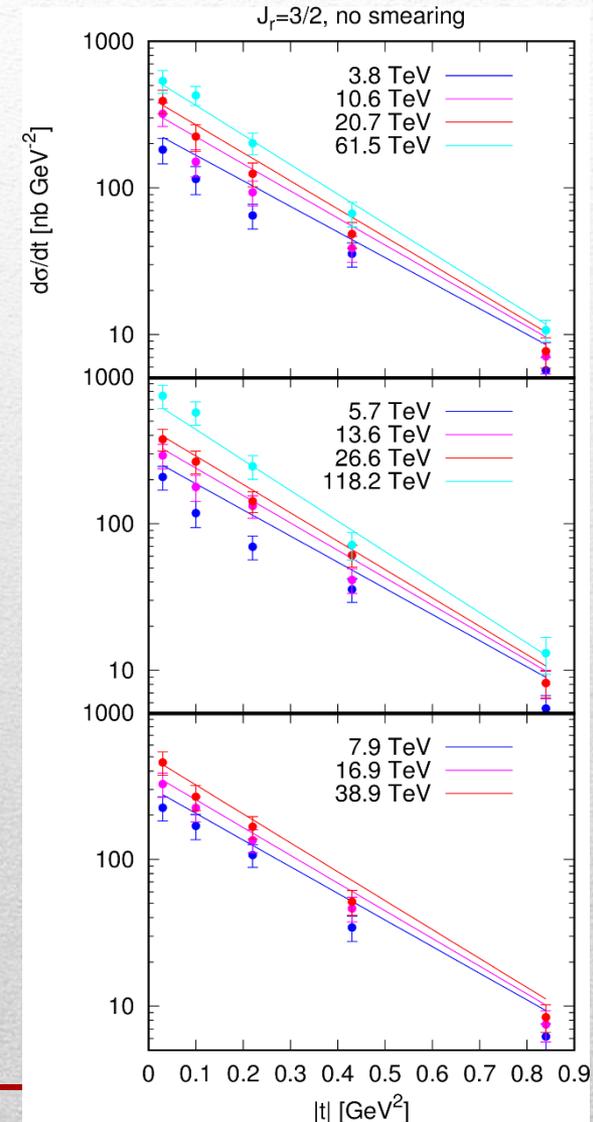

The background is described via an **Effective Pomeron**, whose parameters are fitted to high energy data from Hera

$$\langle \lambda_\psi \lambda_{p'} | T_P | \lambda_\gamma \lambda_p \rangle = iA \left( \frac{s - s_t}{s_0} \right)^{\alpha(t)} e^{b_0(t - t_{\min})} \delta_{\lambda_p \lambda_{p'}} \delta_{\lambda_\psi \lambda_\gamma}$$

Asymptotic + Effective threshold

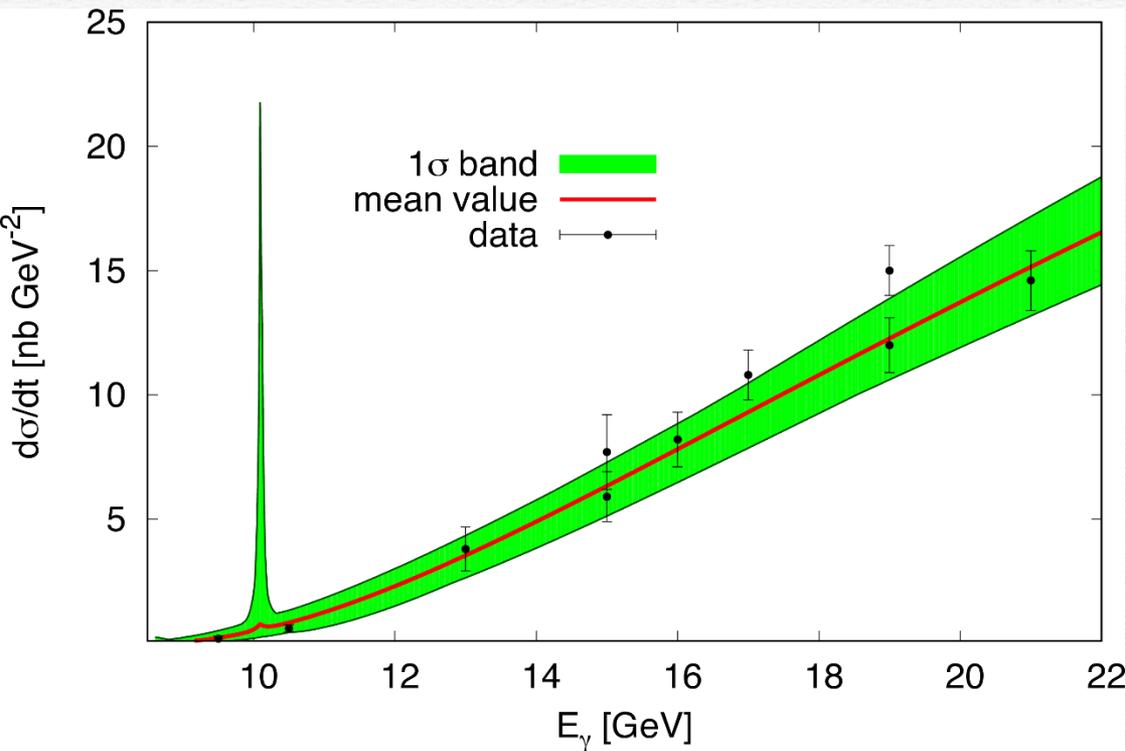

Helicity conservation

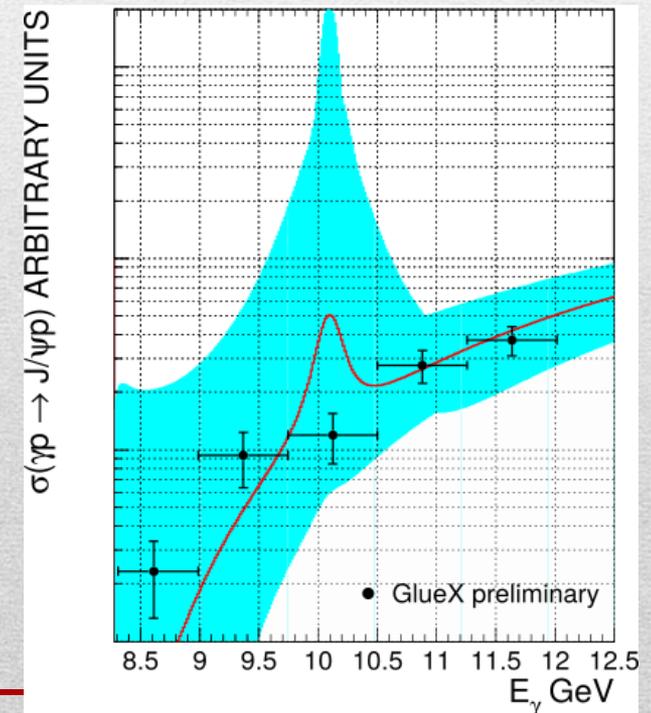

Hiller Blin, AP *et al.* (JPAC), PRD94, 034002

# Pentaquark photoproduction

$$J^P = (3/2)^-$$

$\sigma_s$ (MeV)	0	60
$A$	$0.156^{+0.029}_{-0.020}$	$0.157^{+0.039}_{-0.021}$

Hiller Blin, AP *et al.* (JPAC), PRD94, 034002

# Lineshapes at 4260

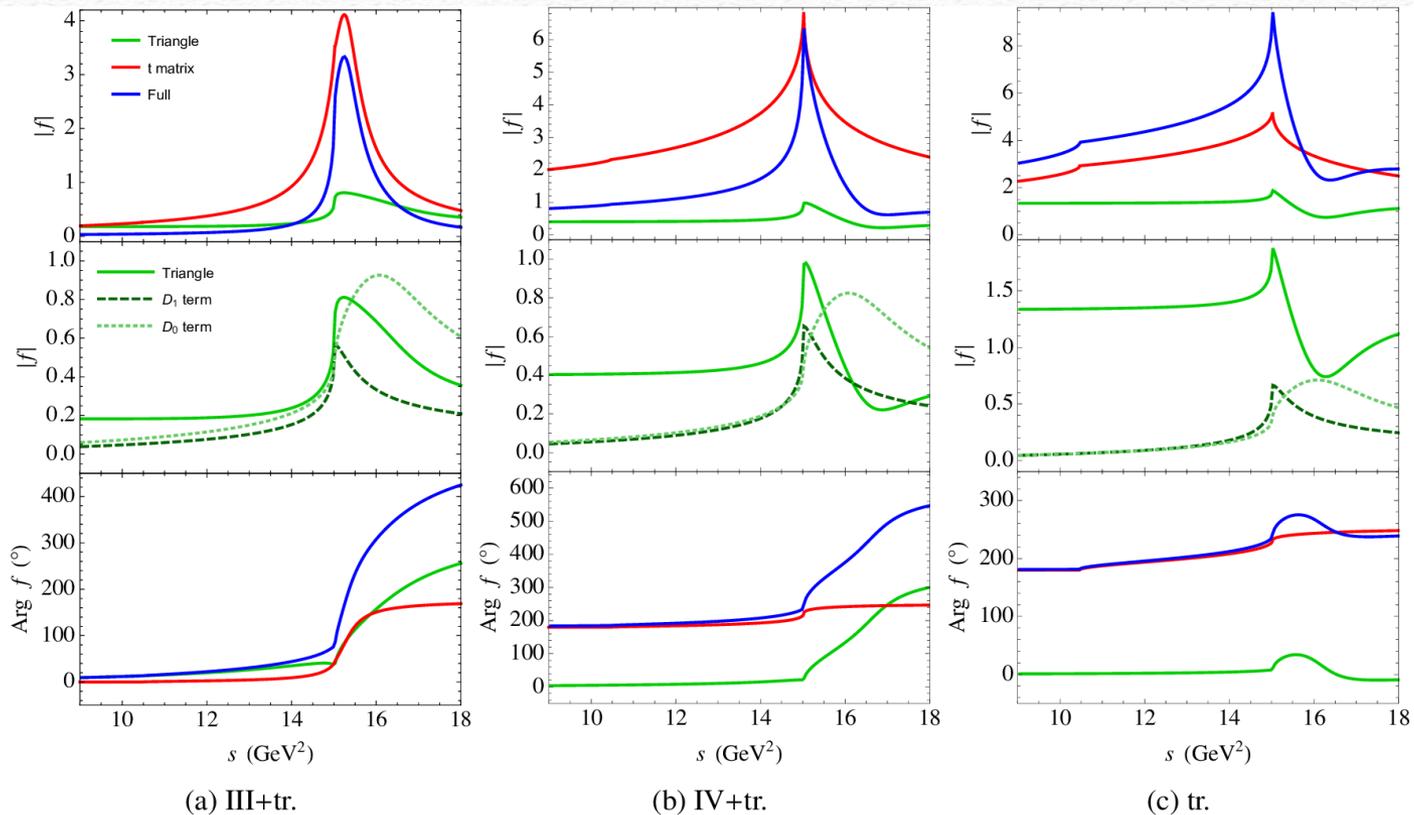

Figure 7: Interplay of scattering amplitude poles and triangle singularity to reconstruct the peak. We focus on the  $J/\psi\pi\pi$  channel, at  $E_{CM} = 4.26$  GeV. The red curve is the  $t_{12}$  scattering amplitude, the green curve is the  $c_1 + H(s, D_1) + H(s, D_0)$  term in Eq. (9), and the blue curve is the product of the two. The upper plots show the magnitudes of these terms, the lower plots the phases. The middle row shows the contributions to the unitarized term due to the  $D_1$  (dashed) and the  $D_0$  (dotted). Only for  $D_1$  the singularity is close enough to the physical region to generate a large peak. (a) The pole on the III sheet generates a narrow Breit-Wigner-like peak. The contribution of the triangle is not particularly relevant. (b) The sharp cusp in the scattering amplitude is due to the IV sheet pole close by; the triangle contributes to make the peak sharper. (c) The scattering amplitude has a small cusp due to the threshold factor, and the triangle is needed to make it sharp enough to fit the data.

# Lineshapes at 4230

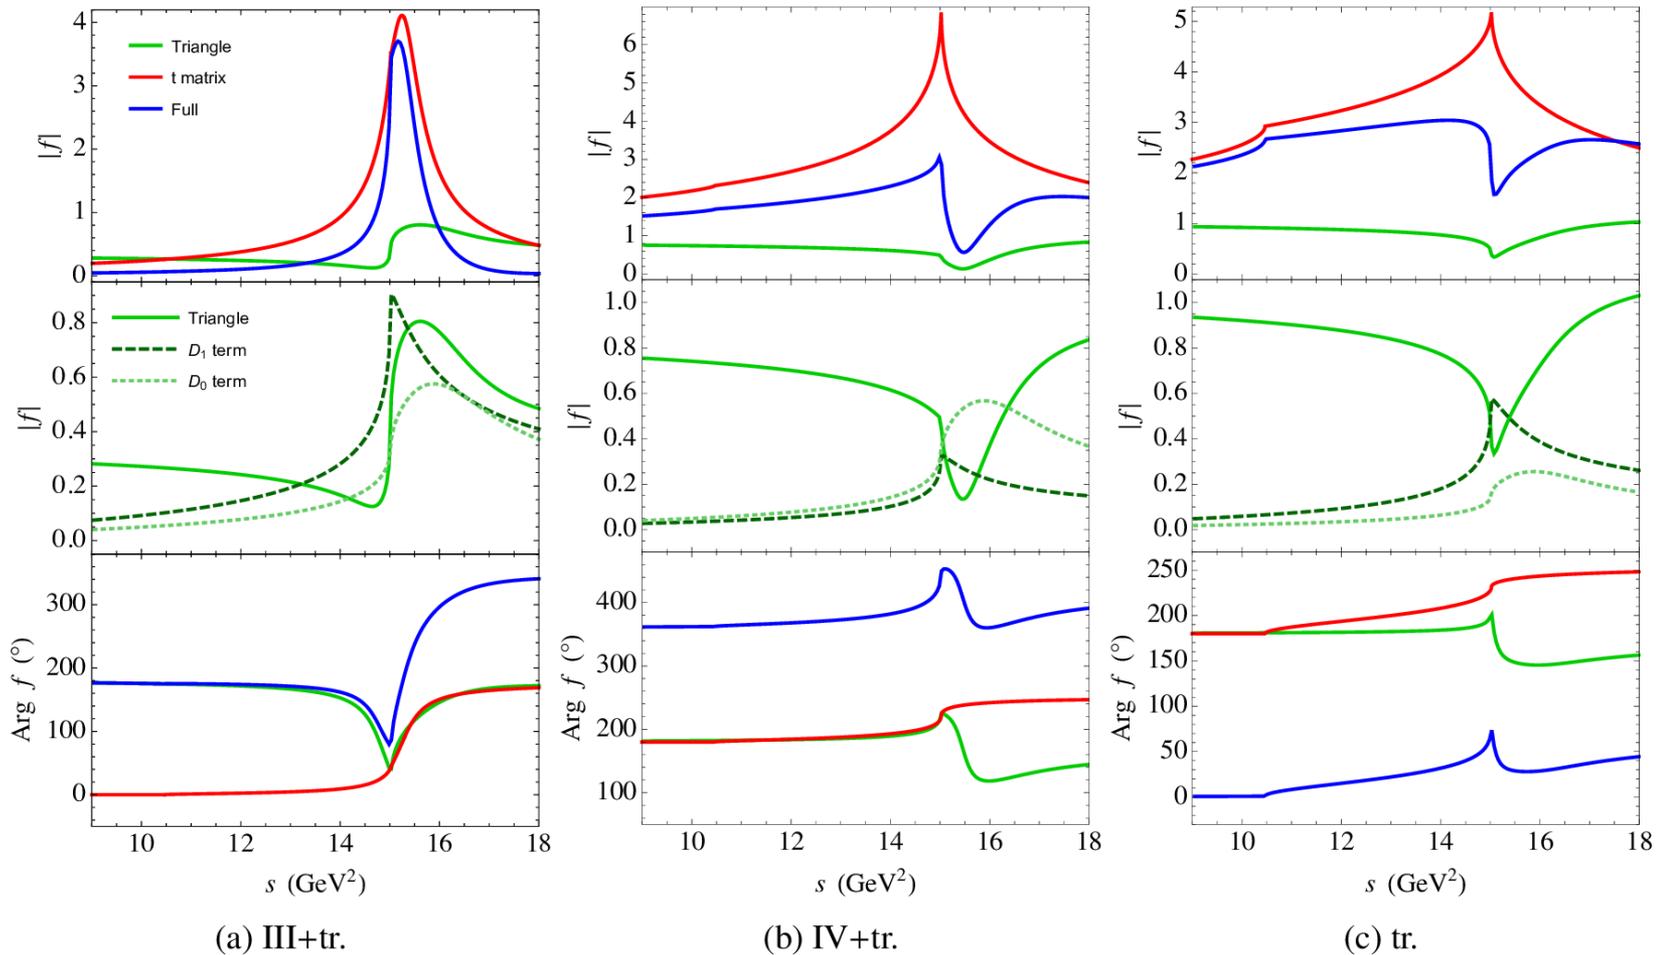

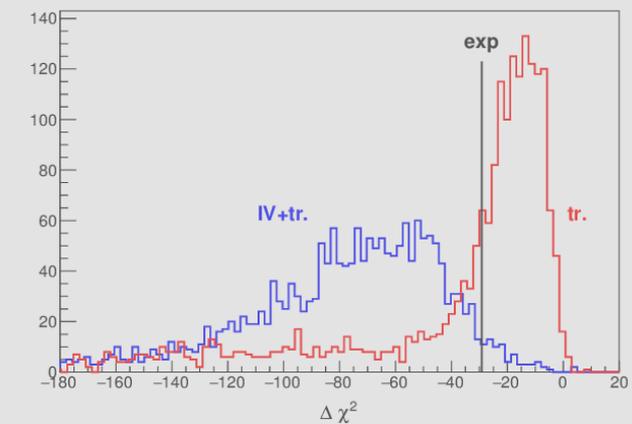

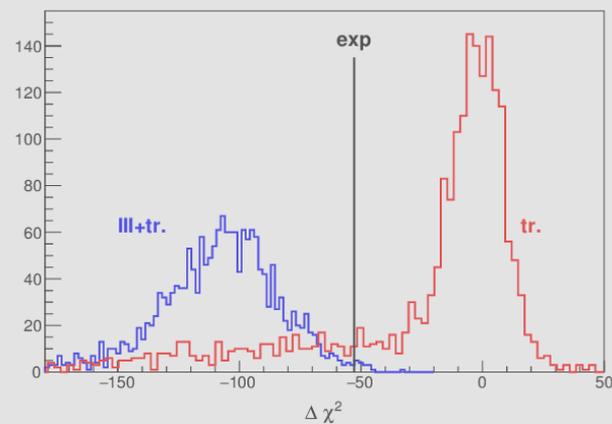

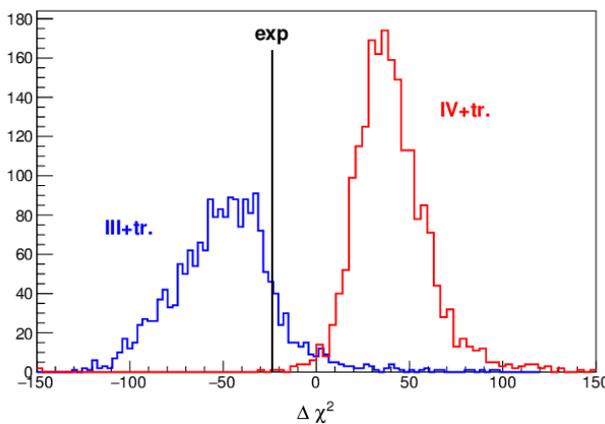

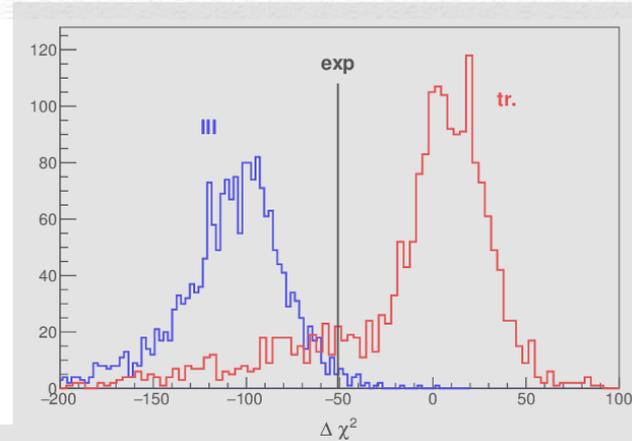

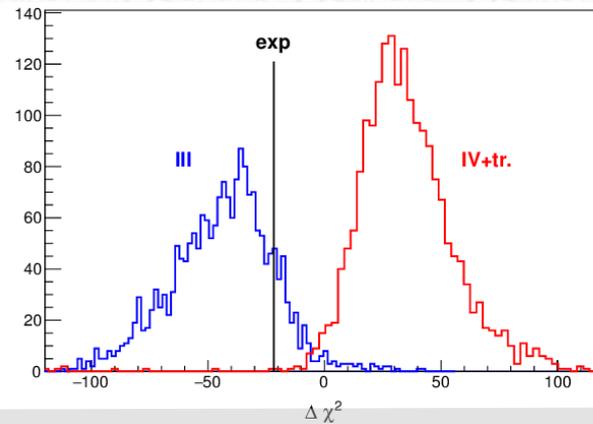

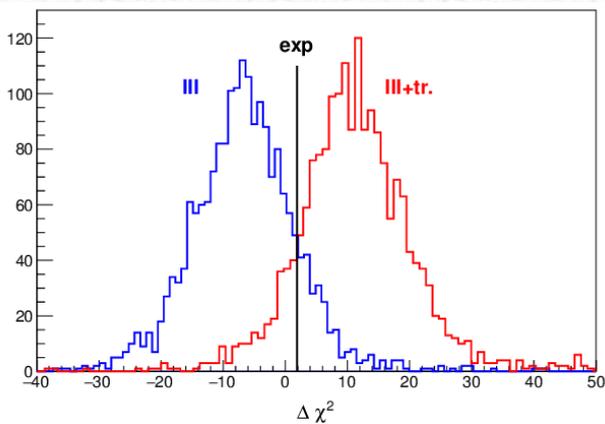

Figure 8: Same as Figure 7, but for  $E_{CM} = 4.23$  GeV.

# Statistical analysis

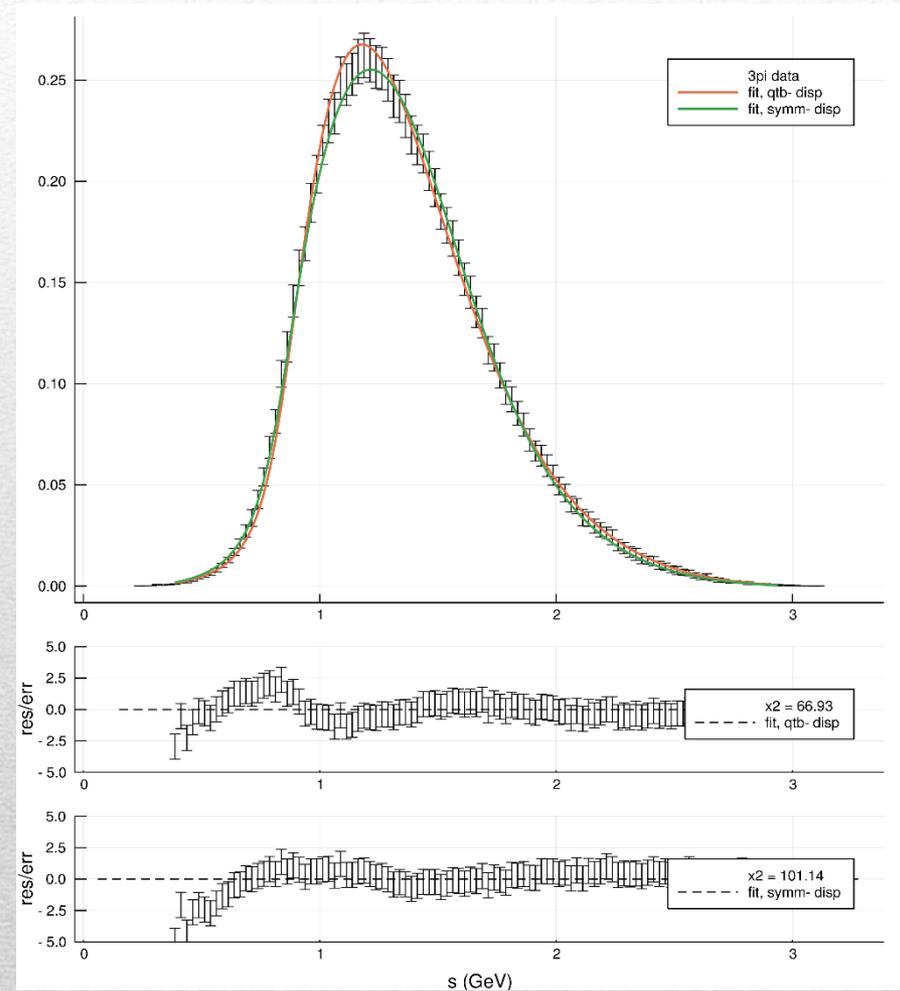

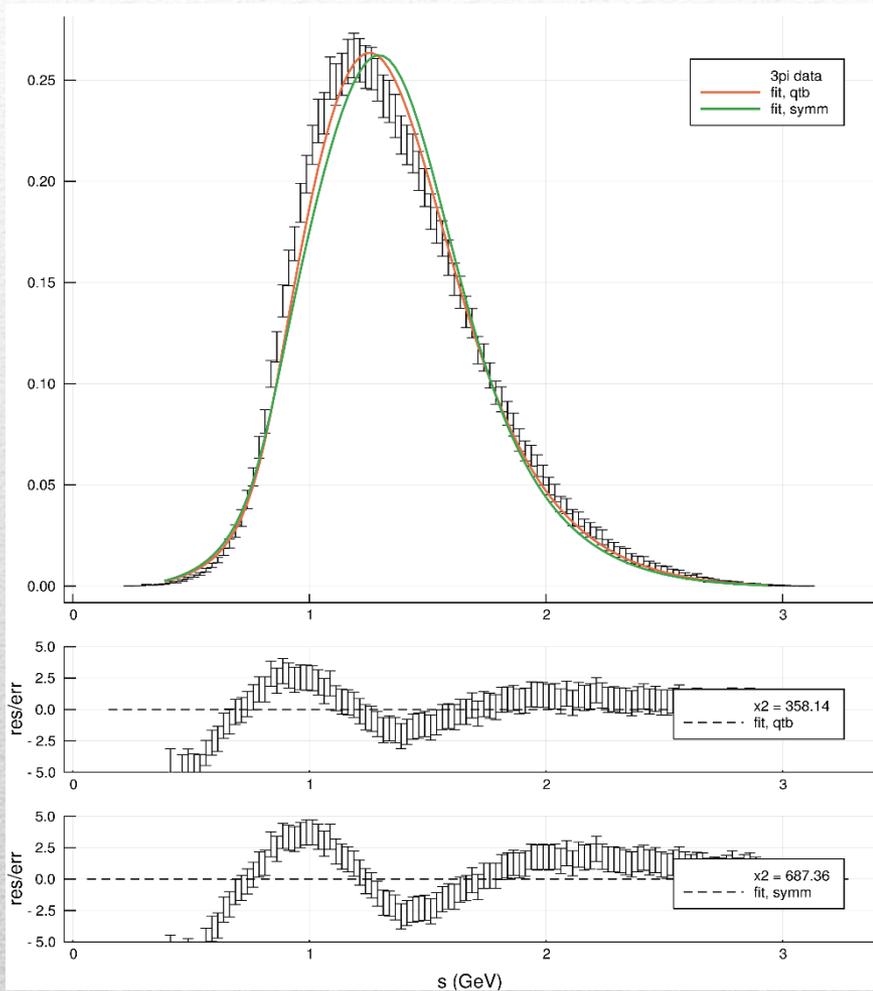

Toy experiments according to the different hypotheses, to estimate the relative rejection of various scenarios

Scenario	III+tr.	IV+tr.	tr.
III	$1.5\sigma$ ( $1.5\sigma$ )	$1.5\sigma$ ( $2.7\sigma$ )	" $2.4\sigma$ " (" $1.4\sigma$ ")
III+tr.	—	$1.5\sigma$ ( $3.1\sigma$ )	" $2.6\sigma$ " (" $1.3\sigma$ ")
IV+tr.			" $2.1\sigma$ " (" $0.9\sigma$ ")

**Not conclusive at this stage**

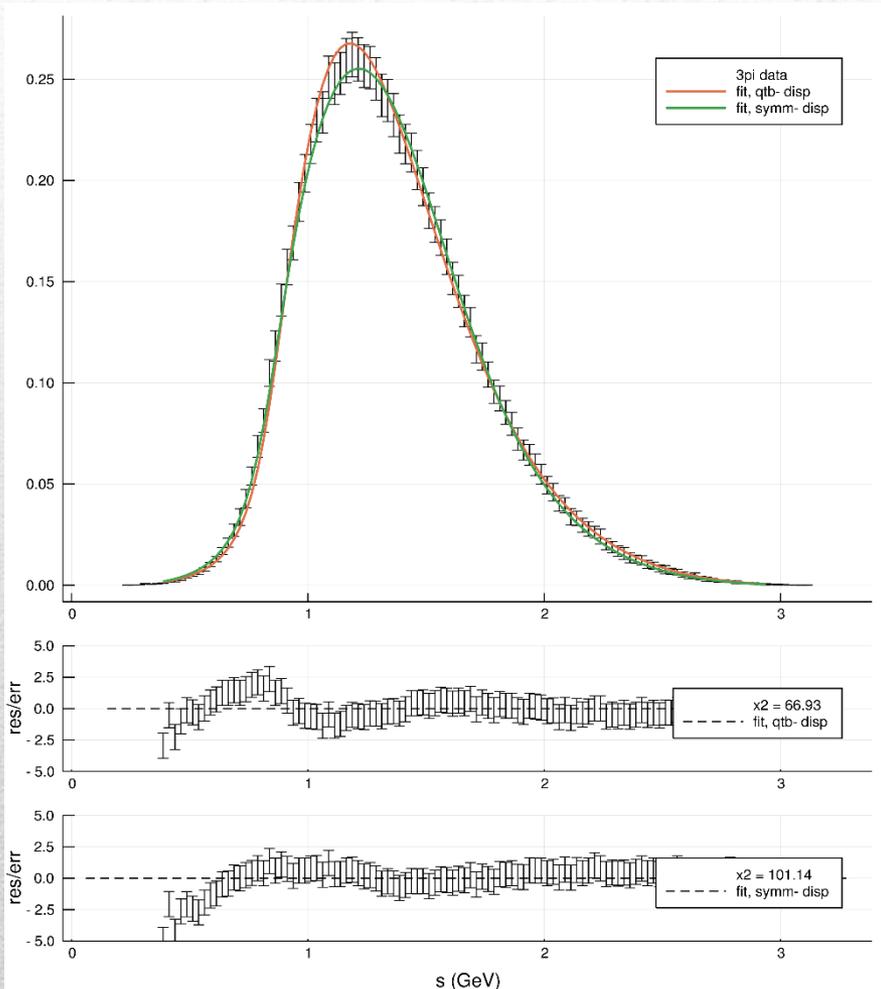

# The $a_1(1260)$

M. Mikhasenko, A. Jackura, AP, *et al.*, in preparation

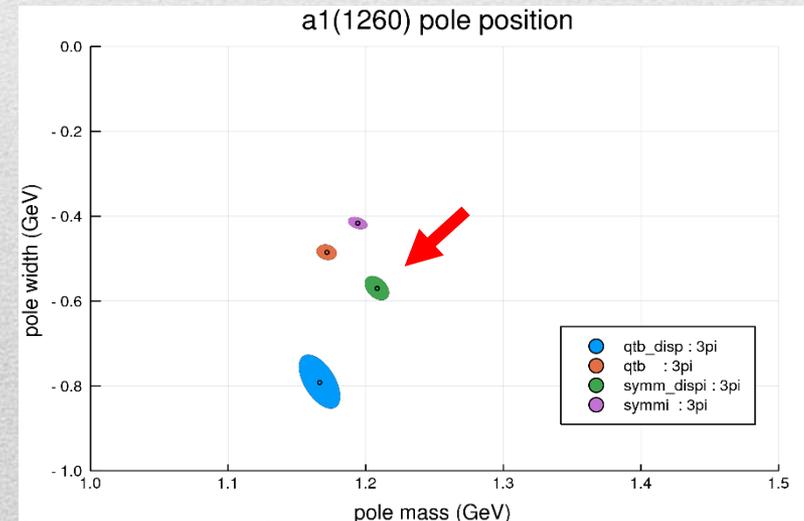

# The $a_1(1260)$

M. Mikhasenko, A. Jackura, AP, *et al.*, in preparation

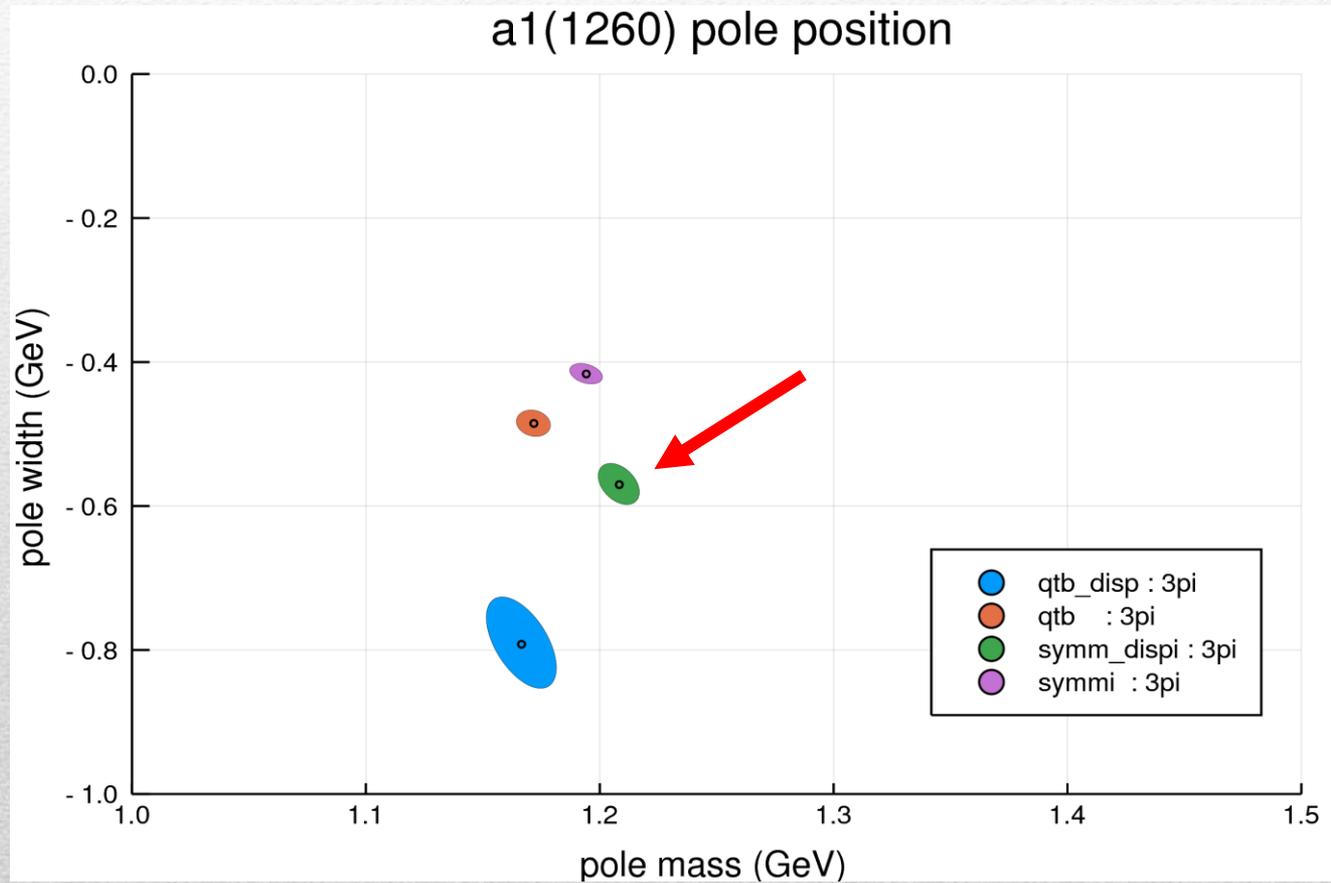

We can use these models to fit  $\tau^- \rightarrow 2\pi^- \pi^+ \nu$  and describe the  $a_1(1260)$

The dispersed improved model describes better the data at threshold

# The $a_1(1260)$

M. Mikhasenko, A. Jackura, AP, *et al.*, in preparation

# The $Y(4260)$

A. Amor, C. Fernandez-Ramirez, AP, U. Tamponi, in preparation

$$f(s) = \frac{N(s)}{K^{-1}(s) - \frac{i}{2}\rho_3(s)},$$

Same game,  
we start analyzing the single channel  
 $e^+e^- \rightarrow J/\psi \pi\pi$  data

$$i\rho_3(s) = \sum_{k=0}^{n-1} a_k (s - s_0)^k + \frac{(s - s_0)^n}{\pi} \int_{(2m_\pi + M_\psi)^2}^{\infty} \frac{\rho_2(s')}{(s' - s)(s' - s_0)^n} ds'$$

$$\rho_2(s') = \int_{4m_\pi^2}^{(\sqrt{s'} - M_\psi)^2} \frac{ds_{\pi\pi}}{2\pi} \frac{\lambda^{1/2}(s', s_{\pi\pi}, m_{J/\psi}^2)}{8\pi s'} \frac{\lambda^{1/2}(s_{\pi\pi}, m_\pi^2, m_\pi^2)}{8\pi s_{\pi\pi}} |t_{2 \rightarrow 2}(s_{\pi\pi})|^2$$

We consider the amplitude in the  
elastic, quasi two-body  
approximation

Need model for the Dalitz distribution

# Three-Body Unitarity

Imaginary parts of  $B, \tau, S$  are fixed by unitarity and matching  
(for simplicity  $v = \lambda$ )

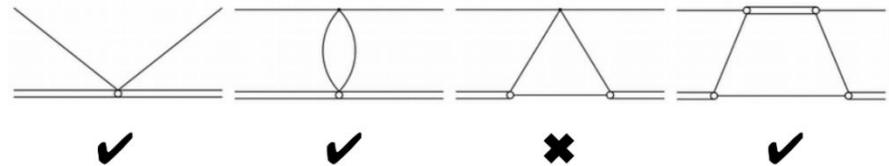

$$\tau(\sigma(k)) = (2\pi)\delta^+(k^2 - m^2)S(\sigma(k))$$

$$-\frac{1}{S(P^2)} = \sigma(k) - M_0^2 - \frac{1}{(2\pi)^3} \int d^3\ell \frac{\lambda^2}{2E_\ell(\sigma(k) - 4E_\ell^2 + i\epsilon)}$$

- in the rest-frame of isobar (**Lorentz invariance!**)
- twice subtracted dispersion relation in  $\sigma(k)=(P-k)^2$

$$\langle q|B(s)|p\rangle = -\frac{\lambda^2}{2\sqrt{m^2+Q^2}(E_Q - \sqrt{m^2+Q^2} + i\epsilon)}$$

- un-subtracted dispersion relation
- one- $\pi$  exchange in TOPT
- real contributions can be added to B

The freedom of adding real terms to  $B$  allows us to use this solution as a flexible parametrization

Numerics in progress:

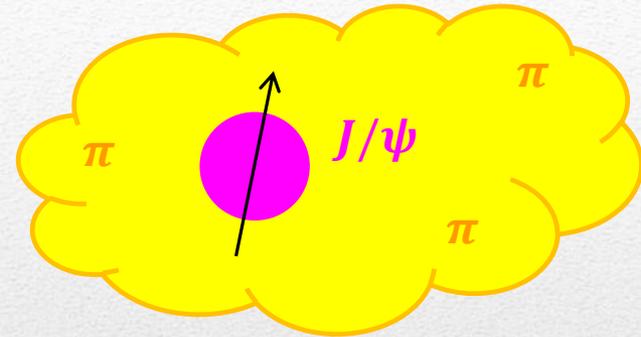

- D. Sadasivan, M. Mai, AP, M. Doring, A. Szczepaniak for the  $a_1(1260)$  and  $a_1(1420)$

Alternative approach based on  $N/D$ :

- A. Jackura, AP et al. (JPAC) for the  $X(3872)$
- J.M. Alarcon, E. Passemar, AP, C. Weiss for the nucleon isoscalar vector form factor

# Hadro-charmonium

Dubynskiy, Voloshin, PLB 666, 344  
Dubynskiy, Voloshin, PLB 671, 82  
Li, Voloshin, MPLA29, 1450060

Born in the context of QCD multipole expansion

$$H_{eff} = -\frac{1}{2} a_{\psi} E_i^a E_i^a$$
$$a_{\psi} = \langle \psi | (t_c^a - t_{\bar{c}}^a) r_i G r_i (t_c^a - t_{\bar{c}}^a) | \psi \rangle$$

the chromoelectric field interacts with soft light matter (highly excited light hadrons)

A bound state can occur via Van der Waals-like interactions

Expected to decay into core charmonium + light hadrons,  
Decay into open charm exponentially suppressed

# Counting rules

Brodsky, Lebed PRD91, 114025

- Exotic states can be produced in threshold regions in  $e^+e^-$ , electroproduction, hadronic beam facilities and are best characterized by cross section ratios
- Two examples:

$$1) \frac{\sigma(e^+e^- \rightarrow Z_c^+ \pi^-)}{\sigma(e^+e^- \rightarrow \mu^+ \mu^-)} \propto \frac{1}{s^6} \text{ as } s \rightarrow \infty$$

$$2) \frac{\sigma(e^+e^- \rightarrow Z_c^+(\bar{c}c\bar{d}u) + \pi^-(\bar{u}d))}{\sigma(e^+e^- \rightarrow \Lambda_c(cud) + \bar{\Lambda}_c(\bar{c}\bar{u}\bar{d}))} \rightarrow \text{const as } s \rightarrow \infty$$

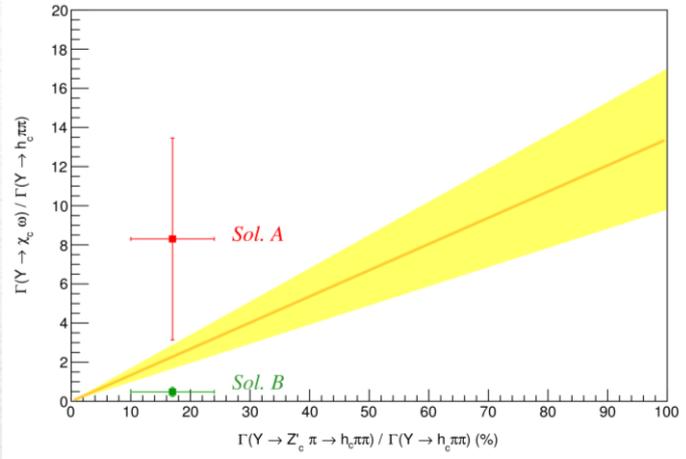

- Ratio numerically smaller if  $Z_c$  behaves like weakly-bound dimeson molecule instead of diquark-antidiquark bound state due to weaker meson color van der Waals forces

Different estimates close to thresholds, and in presence of annihilating  $q \bar{q}$

Guo, Meissner, Wang, Yang, 1607.04020

Voloshin PRD94, 074042

# Tetraquark: the $Y(4220)$

$$\langle \chi_{c0}(p) \omega(\eta, q) | Y(\lambda, P) \rangle = g_\chi \eta \cdot \lambda,$$

$$\langle Z'_c(\eta, q) \pi(p) | Y(\lambda, P) \rangle = g_Z \eta \cdot \lambda \frac{P \cdot p}{f_\pi M_Y},$$

$$\langle h_c(\eta, q) \sigma(p) | Y(\lambda, P) \rangle = g_h \varepsilon_{\mu\nu\rho\sigma} \eta^\mu \lambda^\nu \frac{P^\rho q^\sigma}{P \cdot q},$$

$$\langle \pi(q) \pi(p) | \sigma(P) \rangle = \frac{P^2}{2f_\pi},$$

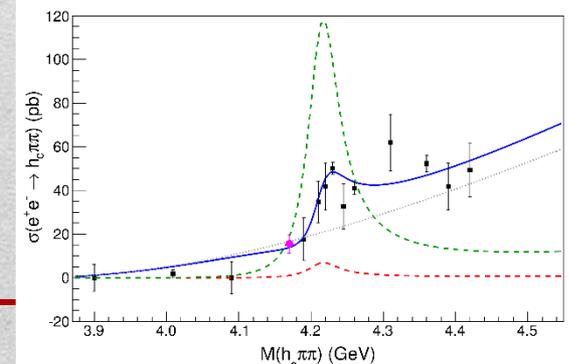

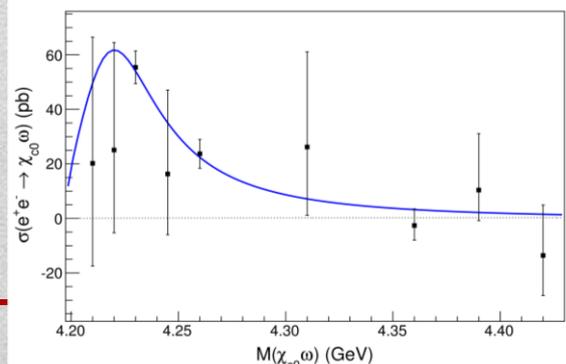

$$\frac{\Gamma(Y(4220) \rightarrow \chi_{c0} \omega)}{\Gamma(Y(4220) \rightarrow h_c \pi^+ \pi^-)} = (13.4 \pm 3.6) \times R_{YZ} = 2.3 \pm 1.2.$$

$$\frac{\Gamma(Y(4220) \rightarrow Z'_c{}^\pm \pi^\mp \rightarrow h_c \pi^+ \pi^-)}{\Gamma(Y(4220) \rightarrow h_c \sigma \rightarrow h_c \pi^+ \pi^-)} = 4.8 \pm 3.5,$$

A state apparently breaking HQSS has been observed

Compatible to be the  $Y_3$  state

Faccini, Filaci, Guerrieri, AP, Polosa, PRD 91, 117501

# Tetraquark: the $b$ sector

Ali, Maiani, Piccinini, Polosa, Riquer PRD91 017502

$$\begin{aligned}M(Z'_b) - M(Z_b) &= 2\kappa_b \\M(Z'_c) - M(Z_c) &= 2\kappa_c \sim 120 \text{ MeV} \\ \kappa_b : \kappa_c &= M_c : M_b \sim 0.30\end{aligned}$$

$$2\kappa_b \sim 36 \text{ MeV, vs. } 45 \text{ MeV (exp.)}$$

$$\begin{aligned}Z_b &= \frac{\alpha |1_{q\bar{q}}0_{b\bar{b}}\rangle - \beta |0_{q\bar{q}}1_{b\bar{b}}\rangle}{\sqrt{2}} \\ Z'_b &= \frac{\alpha |1_{q\bar{q}}0_{b\bar{b}}\rangle + \beta |0_{q\bar{q}}1_{b\bar{b}}\rangle}{\sqrt{2}}\end{aligned}$$

Data on  $\Upsilon(5S) \rightarrow \Upsilon(nS)\pi\pi$  and  $\Upsilon(5S) \rightarrow h_b(nP)\pi\pi$  strongly favor  $\alpha = \beta$

---

# $Z_c(3900) \rightarrow \eta_c \rho$

Esposito, Guerrieri, AP, PLB 746, 194-201

$$\frac{\mathcal{BR}(Z_c \rightarrow \eta_c \rho)}{\mathcal{BR}(Z_c \rightarrow J/\psi \pi)} = (4.6_{-1.7}^{+2.5}) \times 10^{-2}; \quad \frac{\mathcal{BR}(Z_c' \rightarrow \eta_c \rho)}{\mathcal{BR}(Z_c' \rightarrow h_c \pi)} = (1.0_{-0.4}^{+0.6}) \times 10^{-2}.$$

$$\frac{\mathcal{BR}(Z_c \rightarrow h_c \pi)}{\mathcal{BR}(Z_c' \rightarrow h_c \pi)} = 0.34_{-0.13}^{+0.21}; \quad \frac{\mathcal{BR}(Z_c \rightarrow J/\psi \pi)}{\mathcal{BR}(Z_c' \rightarrow J/\psi \pi)} = 0.35_{-0.21}^{+0.49}$$

# Dynamical movie

$Z^+(4430)$

Brodsky, Hwang, Lebed PRL 113 112001

- Since this is still a  $\mathbf{3} \leftrightarrow \bar{\mathbf{3}}$  color interaction, just use the Cornell potential:

$$V(r) = -\frac{4}{3} \frac{\alpha_s}{r} + br + \frac{32\pi\alpha_s}{9m_{cq}^2} \left(\frac{\sigma}{\sqrt{\pi}}\right)^3 e^{-\sigma^2 r^2} \mathbf{S}_{cq} \cdot \mathbf{S}_{\bar{c}\bar{q}},$$

e.g. Barnes *et al.*, PRD 72, 054026

- Use that the kinetic energy released in  $\bar{B}^0 \rightarrow K^- Z^+(4430)$  converts into potential energy until the diquarks come to rest
- Hadronization most effective at this point (WKB turning point)

$$r_Z = 1.16 \text{ fm}, \langle r_{\psi(2S)} \rangle = 0.80 \text{ fm}, \langle r_{J/\psi} \rangle = 0.39 \text{ fm}$$

$$\frac{B(Z^+(4430) \rightarrow \psi(2S)\pi^+)}{B(Z^+(4430) \rightarrow J/\psi \pi^+)} \sim 72$$

( $> 10 \text{ exp.}$ )

# Towards hybridized tetraquarks

Esposito, AP, Polosa, PLB758, 292

The absence of many of the predicted states might point to the need for **selection rules**

It is unlikely that the **many close-by thresholds** play no role whatsoever

All the well assessed 4-quark resonances lie close and **above** some meson-meson thresholds:

We introduce a **mechanism** that might provide “dynamical selection rules” to explain the presence/absence of resc

	Thr.	$\delta$ (MeV)	$A \sqrt{\delta}$ (MeV)	$\Gamma$ (MeV)

We introduce a **mechanism** that might provide “dynamical selection rules” to explain the presence/absence of resonances from the experimental data.

# Hybridized tetraquarks

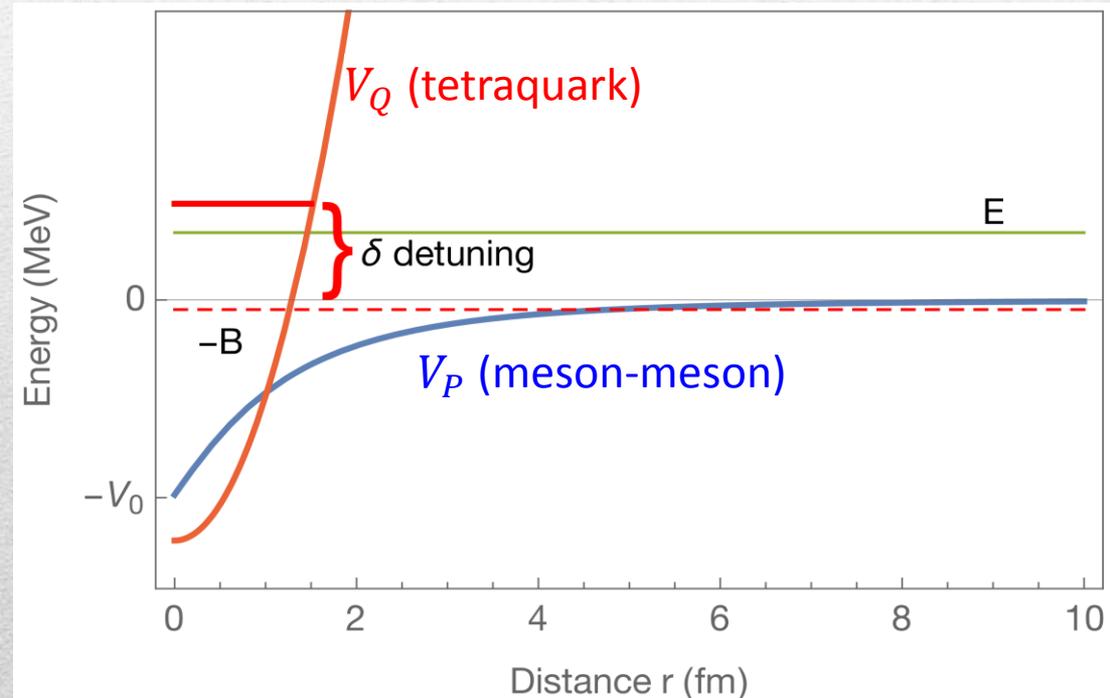

Esposito, AP, Polosa, PLB758, 292

The absence of many of the predicted states might point to the need for **selection rules**

It is unlikely that the **many close-by thresholds** play no role whatsoever

All the well assessed 4-quark resonances lie close and **above** some meson-meson thresholds:

We introduce a **mechanism** that might provide “dynamical selection rules” to explain the presence/absence of resonances from the experimental data

Let  $P$  and  $Q$  be orthogonal subspaces of the Hilbert space

$$H = H_{PP} + H_{QQ}$$

We have the (weak) scattering length  $a_P$  in the open channel.

We add an off-diagonal  $H_{QP}$  which connects the two subspaces

# Hybridized tetraquarks

Esposito, AP, Polosa, PLB758, 292

$$\Gamma = -16\pi^3 \rho \Im(T) \sim 16\pi^4 \rho |H_{PQ}|^2 \delta \left( \frac{p_1^2}{2M} + \frac{p_2^2}{2M} - \delta \right)$$

The expected width is the average **over momenta that allow for the existence of a tetraquark**  $p < \bar{p} = 50 \div 100$  MeV

$$\Gamma \sim A\sqrt{\delta}$$

We therefore expect to see a level if:

- $\delta > 0$  the state **lies above threshold**
- $\delta < \frac{\bar{p}^2}{2M}$ , only the **closest threshold** contributes
- The states  $\psi_Q$  and  $\psi_P$  are **orthogonal**

$X(3872)^+$  falls below threshold,  $M(1^{++}) < M(D^{+*}\bar{D}^0)$

$\delta < 0$ , so  $a > 0 \rightarrow$  **Repulsive interaction**

**No charged partners of the  $X(3872)$ !**

# Hybridized tetraquarks

Esposito, AP, Polosa, PLB758, 292

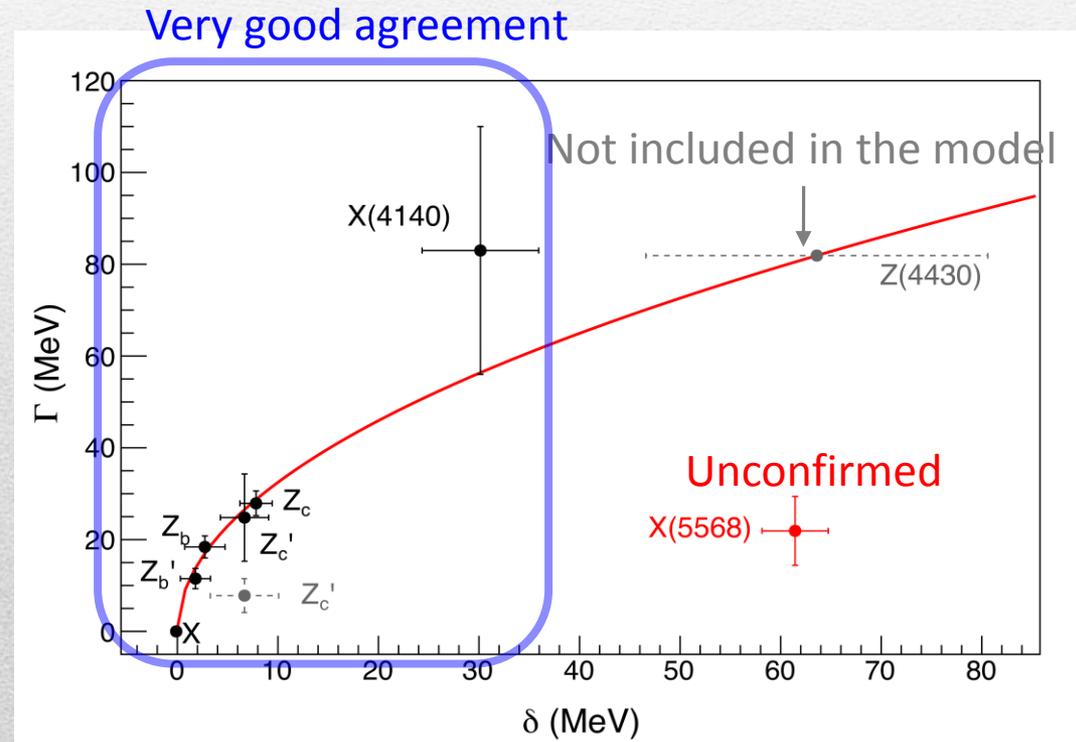

The model works only if no direct transition between closed channel levels can occur  
This prevents the straightforward generalization to  $L = 1$  and radially excited states  
(like the  $Y$ s or the  $Z(4430)$ )

In this picture, a  $[bu][\bar{s}\bar{d}]$  state with resonance parameters of the  $X(5568)$  observed by D0 is not likely

Also, one has to ensure the orthogonality between the two Hilbert subspaces  $P$  and  $Q$ .  
This might affect the estimate for the  $X(4140)$

All the resonances can be fitted with

$$A = (10.3 \pm 1.3) \text{ MeV}^{1/2}$$
$$\chi^2/\text{DOF} = 1.2/5$$

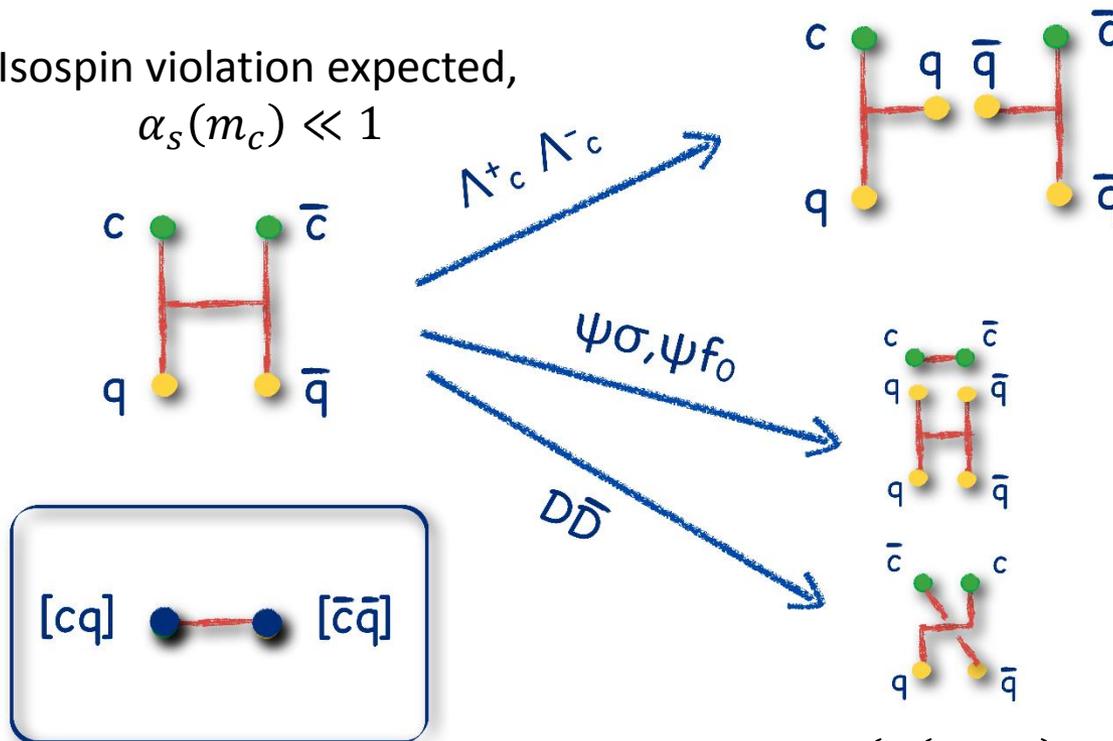

# Baryonium

C. Sabelli

a structure  $[cq][\bar{c}\bar{q}]$  can explain the dominance of baryon channel

Isospin violation expected,  
 $\alpha_s(m_c) \ll 1$

Rossi, Veneziano,  
 NPB 123, 507;  
 Phys.Rept. 63, 149;  
 PLB70, 255

$$\frac{B(Y(4660) \rightarrow \Lambda_c^+ \Lambda_c^-)}{B(Y(4660) \rightarrow \psi(2S)\pi\pi)} = 25 \pm 7$$

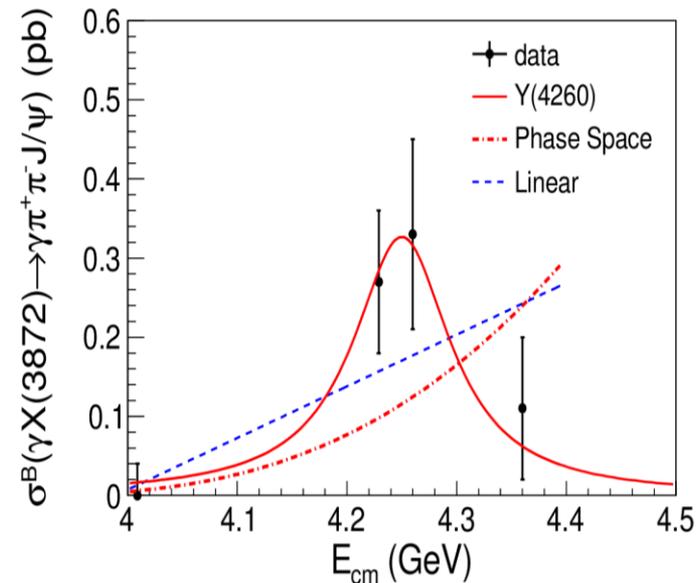

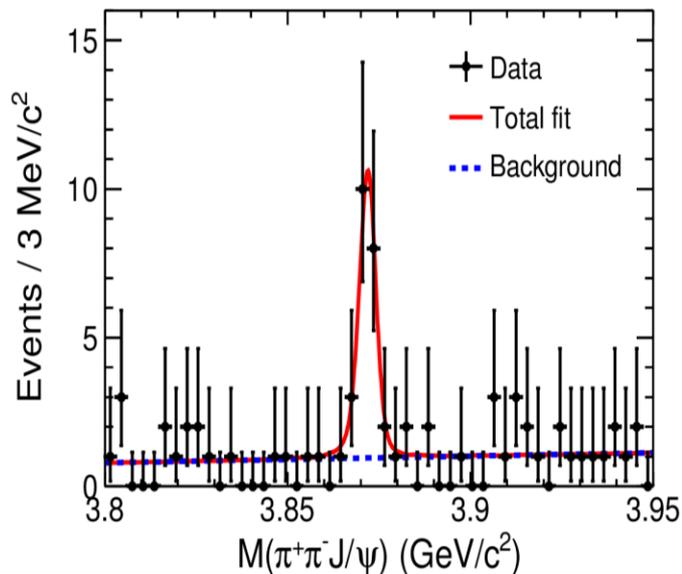

Cotugno, Faccini, Polosa, Sabelli,  
 PRL 104, 132005

# $Y(4260) \rightarrow \gamma X(3872)$

M. Ablikim et al., Phys. Rev. Lett. 112 (2014) 092001

F. Piccinini

BESIII:  $e^+e^- \rightarrow Y(4260) \rightarrow X(3872)\gamma$

With  $\mathcal{B}[X(3872) \rightarrow \pi^+\pi^-J/\psi] = 5\%$

$$\frac{\mathcal{B}[Y(4260) \rightarrow \gamma X(3872)]}{\mathcal{B}[Y(4260) \rightarrow \pi^+\pi^-J/\psi]} = 0.1$$

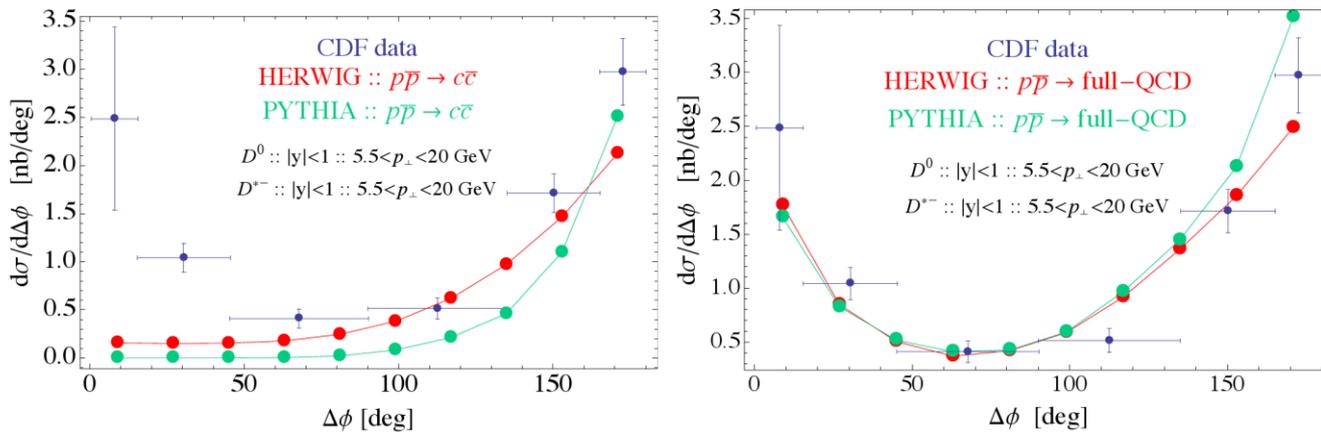

Strong indication that  $Y(4260)$  and  $X(3872)$  share a similar structure

# Tuning of MC

## Monte Carlo simulations

A. Esposito

- We compare the  $D^0 D^{*-}$  pairs produced as a function of relative azimuthal angle with the results from CDF:

*The c-cbar run underestimate the low angles (low- $k_{\perp}$ ) region!*

Such distributions of charm mesons are available at Tevatron  
No distribution has been published (yet) at LHC

# Prompt production of $X(3872)$

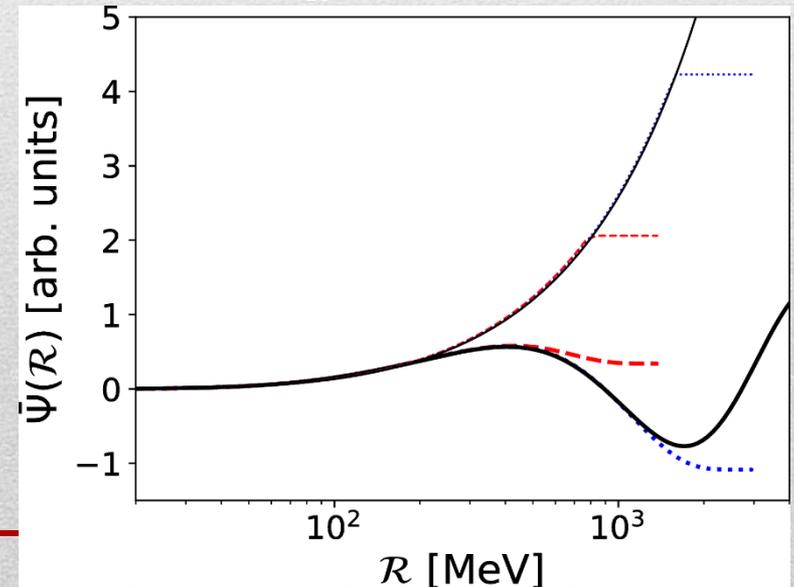

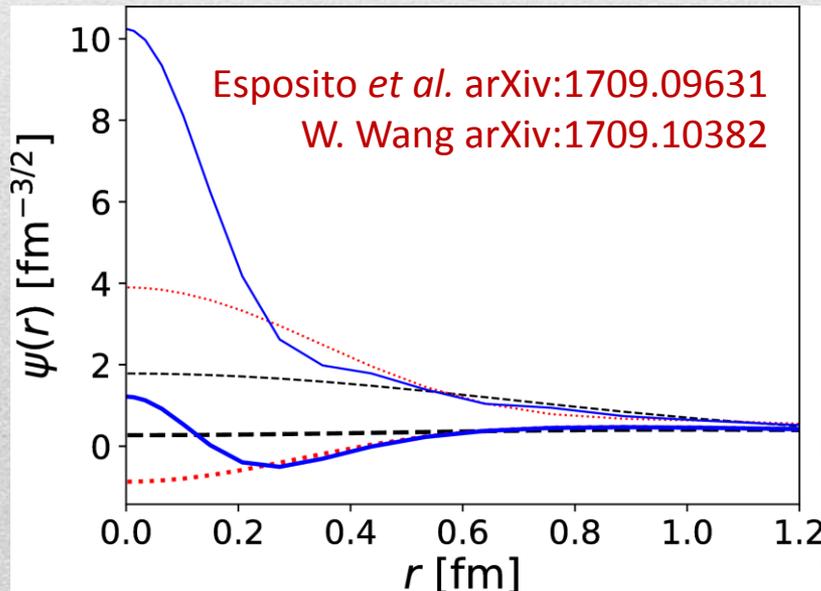

$$\begin{aligned}
 \sigma(\bar{p}p \rightarrow X) &\sim \left| \int d^3\mathbf{k} \langle X | D^0 \bar{D}^{*0}(\mathbf{k}) \rangle \langle D^0 \bar{D}^{*0}(\mathbf{k}) | \bar{p}p \rangle \right|^2 \\
 &\simeq \left| \int_{\mathcal{R}} d^3\mathbf{k} \langle X | D^0 \bar{D}^{*0}(\mathbf{k}) \rangle \langle D^0 \bar{D}^{*0}(\mathbf{k}) | \bar{p}p \rangle \right|^2 \\
 &\leq \int_{\mathcal{R}} d^3\mathbf{k} |\Psi(\mathbf{k})|^2 \int_{\mathcal{R}} d^3\mathbf{k} |\langle D^0 \bar{D}^{*0}(\mathbf{k}) | \bar{p}p \rangle|^2 \\
 &\leq \int_{\mathcal{R}} d^3\mathbf{k} |\langle D^0 \bar{D}^{*0}(\mathbf{k}) | \bar{p}p \rangle|^2
 \end{aligned}$$

The estimate of the  $k_{max}$  has been brought back

*Albaladejo et al. arXiv:1709.09101*

The essence of the argument is that one has to look at the integral of the wave function

$$\int_{\mathcal{R}} d^3\mathbf{k} \psi(\mathbf{k})$$

# Prompt production of $X(3872)$

However, the integral of the wave function may not be well defined.

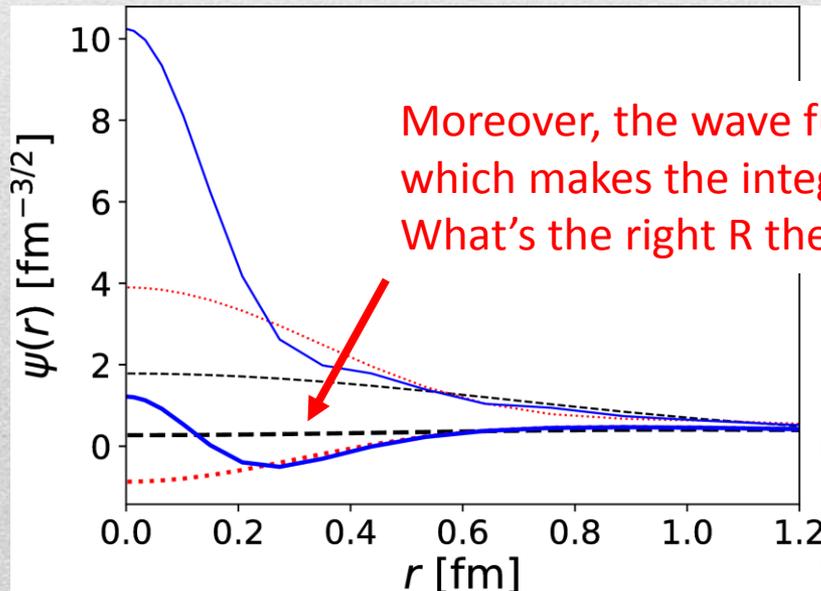

For example, if one considers the wave function in the scattering length approximation,

$$\psi(\mathbf{k}) = \frac{1}{\pi} \frac{a^{3/2}}{a^2 k^2 + 1} \quad \text{it's not integrable}$$

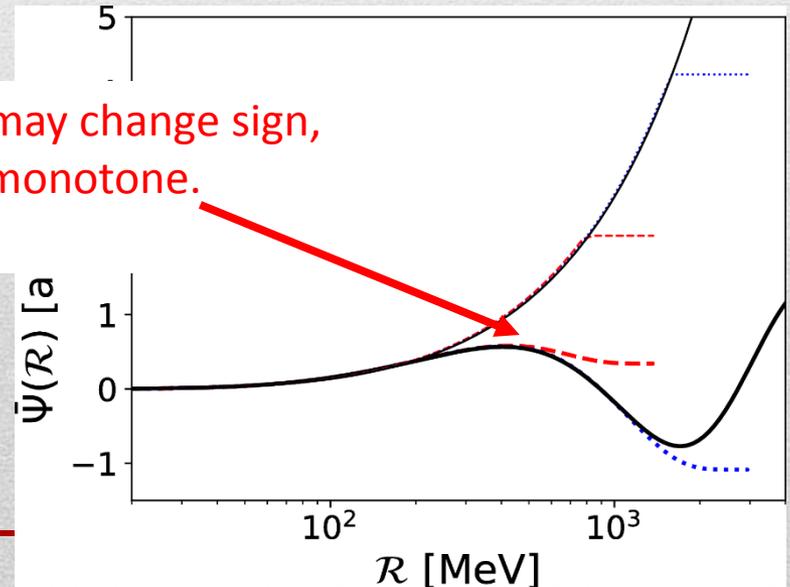

Esposito *et al.* arXiv:1709.09631

A physical value should rather be based on expectation values which involve  $|\psi(\mathbf{k})|^2$

For example, an estimate using the virial theorem gives  $k \sim 100$  MeV for the deuteron

Moreover, the wave function may change sign,  
which makes the integral nonmonotone.  
What's the right R then?

## Note on $X(3872)$ production at hadron colliders and its molecular structure

Miguel Albaladejo,<sup>1</sup> Feng-Kun Guo,<sup>2,3</sup> Christoph Hanhart,<sup>4</sup>

Ulf-G. Meißner,<sup>5,4</sup> Juan Nieves,<sup>6</sup> Andreas Nogga,<sup>4</sup> and Zhi Yang<sup>5</sup>

The production of the  $X(3872)$  as a hadronic molecule in hadron colliders is clarified. We show that the conclusion of Bignamini *et al.*, Phys. Rev. Lett. **103** (2009) 162001, that the production of the  $X(3872)$  at high  $p_T$  implies a non-molecular structure, does not hold. In particular, using the well understood properties of the deuteron wave function as an example, we identify the relevant scales in the production process.

The argument is about the value of a nonnormalizable wave function. Any argument about where the wave function is localized must be calculated for the modulus square

A widespread argument against the interpretation of the  $X(3872)$  as a hadronic molecule is its copious production at hadron colliders. Based on the inequality<sup>1</sup>

$$\sigma(\bar{p}p \rightarrow X) \sim \left| \int d^3\mathbf{k} \langle X | D^0 \bar{D}^{*0}(\mathbf{k}) \rangle \langle D^0 \bar{D}^{*0}(\mathbf{k}) | \bar{p}p \rangle \right|^2$$

## Notes from the Editors: Highlights of the Year

Published December 30, 2013 | *Physics* 6, 139 (2013) | DOI: 10.1103/Physics.6.139

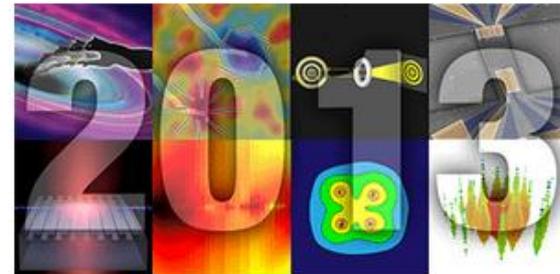

***Physics* looks back at the standout stories of 2013.**

As 2013 draws to a close, we look back on the research covered in *Physics* that really made waves in and beyond the physics community. In thinking about which stories to highlight, we considered a combination of factors: popularity on the website, a clear element of surprise or discovery, or signs that the work could lead to better technology. On behalf of the *Physics* staff, we wish everyone an excellent New Year.

— Matteo Rini and Jessica Thomas

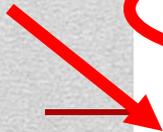

### Four-Quark Matter

Quarks come in twos and threes—or so nearly every experiment has told us. This summer, the BESIII Collaboration in China and the Belle Collaboration in Japan reported they had sorted through the debris of high-energy electron-positron collisions and seen a **mysterious particle** that appeared to contain four quarks. Though other explanations for the nature of the particle, dubbed  $Z_c(3900)$ , are possible, the “tetraquark” interpretation may be gaining traction: BESIII has since **seen** a series of other particles that appear to contain four quarks.

Images from popular *Physics* stories in 2013.

mysterious particle

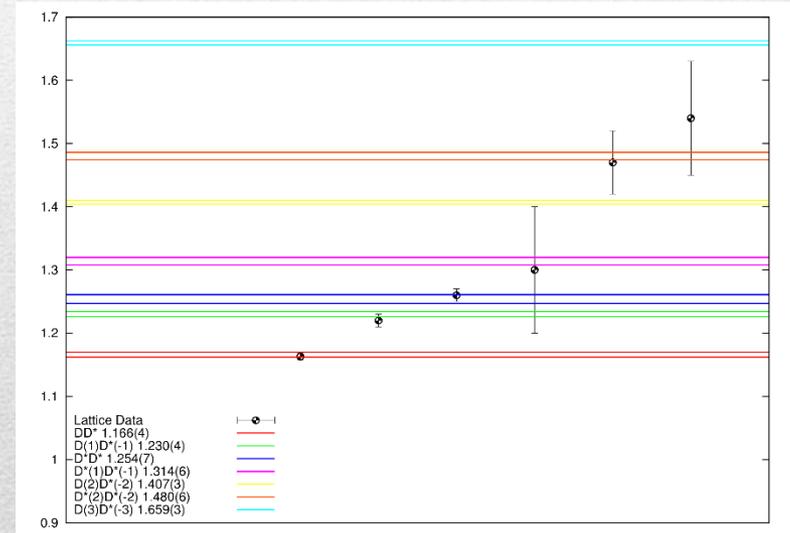

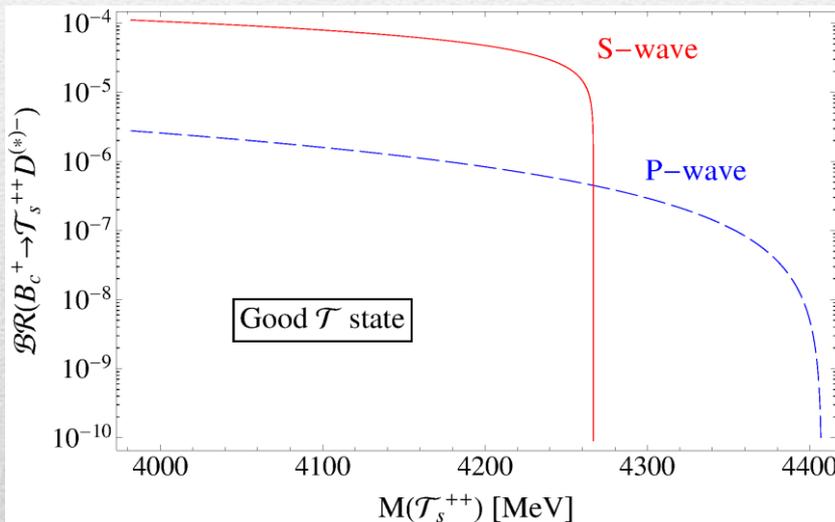

# Doubly charmed states

For example, we proposed to look for **doubly charmed states**, which in tetraquark model are  $[cc]_{S=1}[\bar{q}\bar{q}]_{S=0,1}$

These states could be observed in  $B_c$  decays @LHC and sought on the lattice

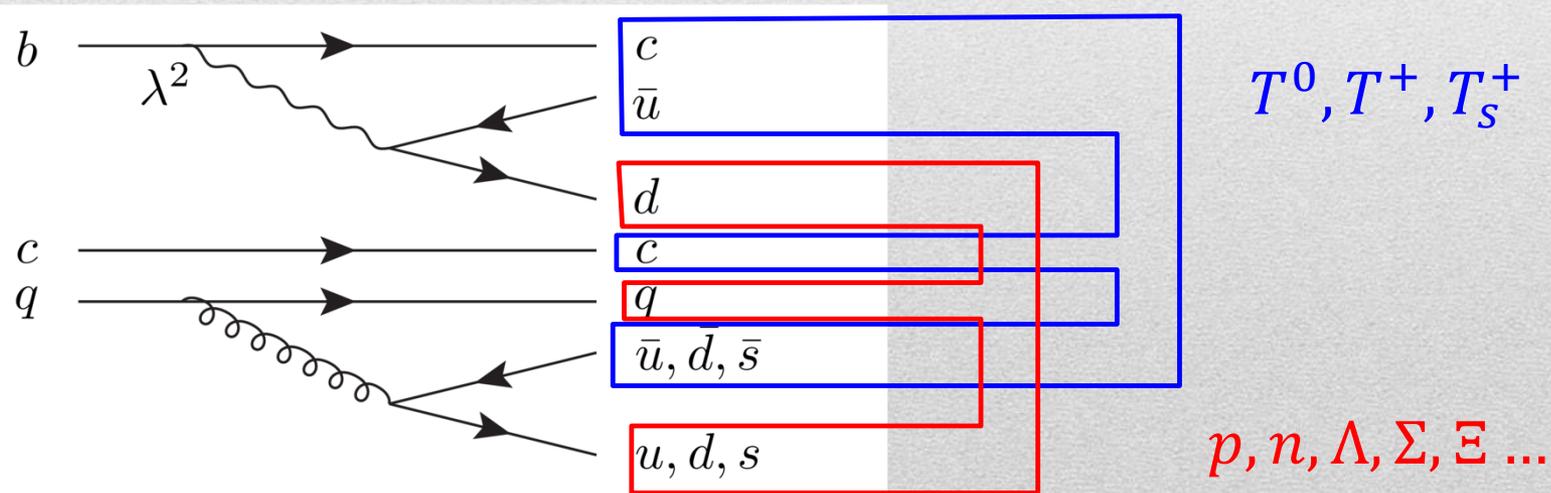

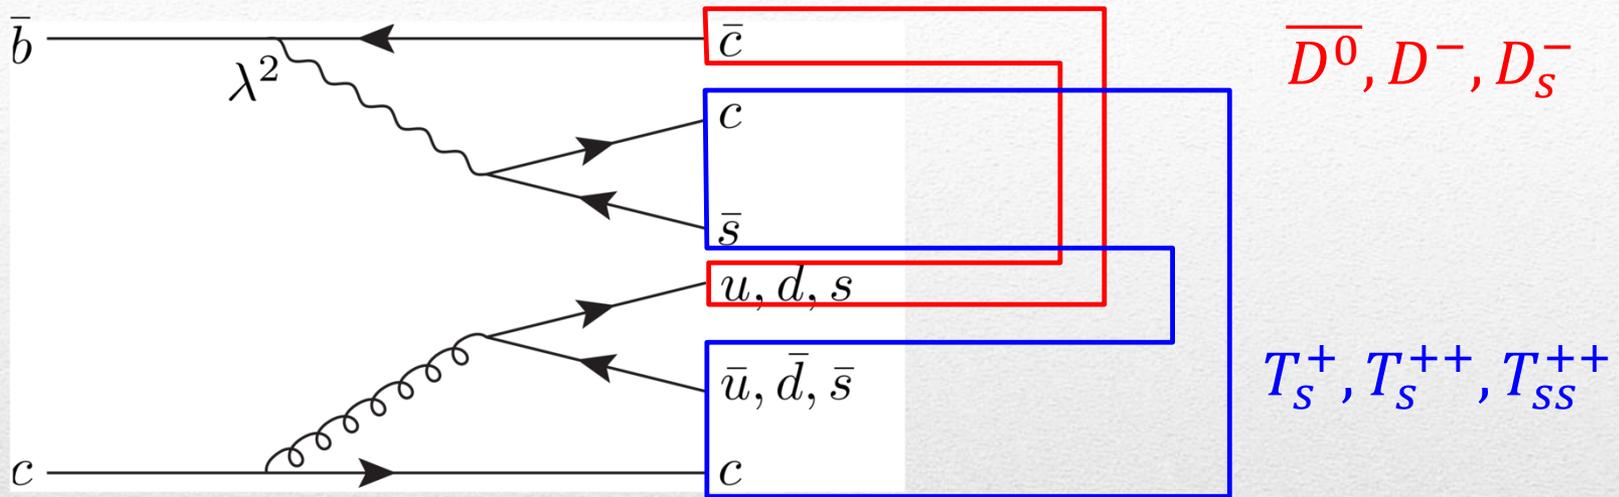

Esposito, Papinutto, AP, Polosa, Tantalò, PRD88 (2013) 054029

Preliminary results on spectrum for  $m_\pi = 490$  MeV,  $32^3 \times 64$  lattice,  $a = 0.075$  fm

Guerrieri, Papinutto, AP, Polosa, Tantalò, PoS LATTICE2014 106

# $T$ states production

$p, n, \Lambda, \Sigma, \Xi \dots$

# Prompt production of $X(3872)$

$X(3872)$  is the Queen of exotic resonances, the most popular interpretation is a  $D^0\bar{D}^{0*}$  molecule (bound state, pole in the 1<sup>st</sup> Riemann sheet?)

We aim to evaluate prompt production cross section at hadron colliders via Monte-Carlo simulations

**Q.** What is a molecule in MC? **A.** «Coalescence» model

$$\sigma(p\bar{p} \rightarrow X(3872)) \sim \int d^3k |\langle X | D\bar{D}^* \rangle \langle D\bar{D}^* | p\bar{p} \rangle|^2 < \int_{k < k_{max}} d^3k |\langle D\bar{D}^* | p\bar{p} \rangle|^2$$

This should provide an upper bound for the cross section

Bignamini, Piccinini, Polosa, Sabelli PRL103 (2009) 162001

Kadastic, Raidan, Strumia PLB683 (2010) 248

# Estimating $k_{max}$

The binding energy is  $E_B \approx -0.16 \pm 0.31$  MeV: **very small!**

In a simple square well model this corresponds to:

$$\sqrt{\langle k^2 \rangle} \approx 50 \text{ MeV}, \sqrt{\langle r^2 \rangle} \approx 10 \text{ fm}$$

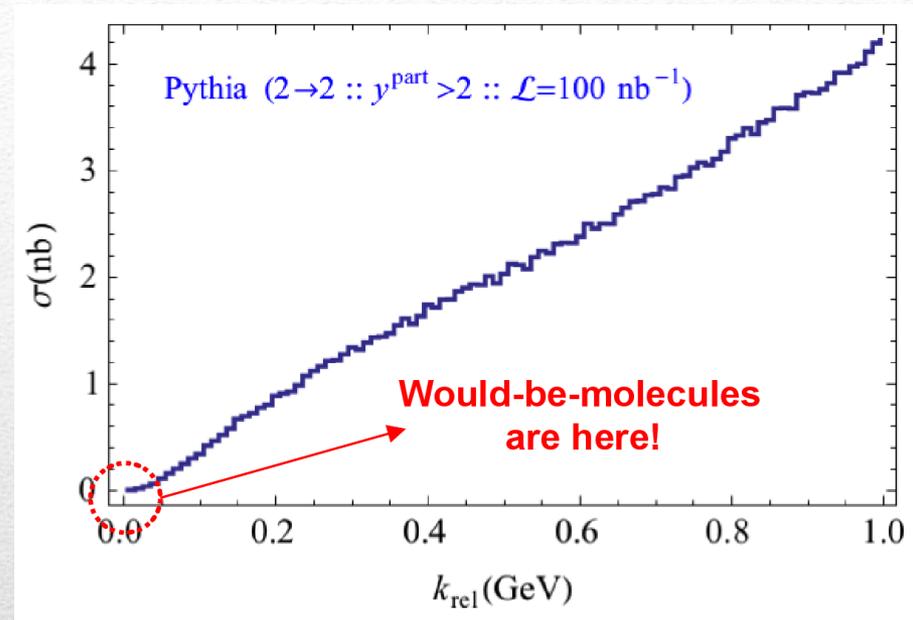

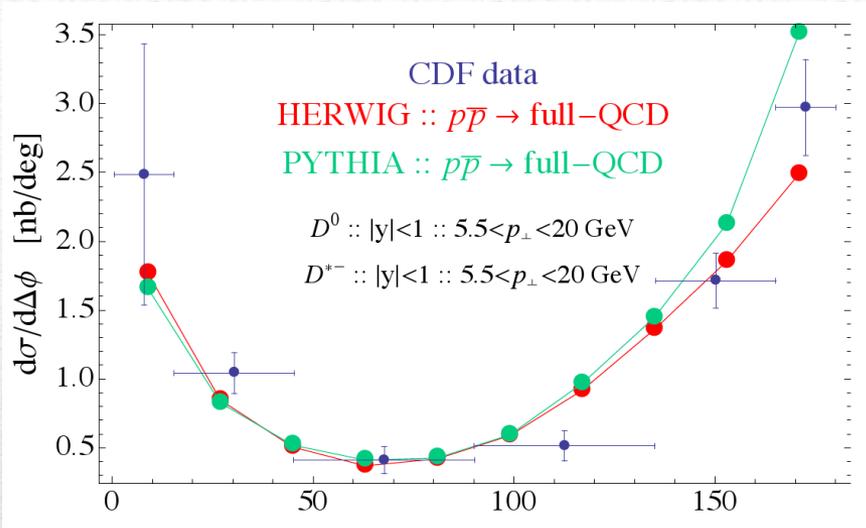

$$\left( \begin{array}{l} \text{binding energy reported in Kamal Seth's talk is } E_B \approx -0.013 \pm 0.192 \text{ MeV:} \\ \sqrt{\langle k^2 \rangle} \approx 30 \text{ MeV}, \sqrt{\langle r^2 \rangle} \approx 30 \text{ fm} \end{array} \right)$$

to compare with deuteron:  $E_B = -2.2$  MeV

$$\sqrt{\langle k^2 \rangle} \approx 80 \text{ MeV}, \sqrt{\langle r^2 \rangle} \approx 4 \text{ fm}$$

We assume  $k_{max} \sim \sqrt{\langle k^2 \rangle} \approx 50$  MeV, some other choices are commented later

# 2009 results

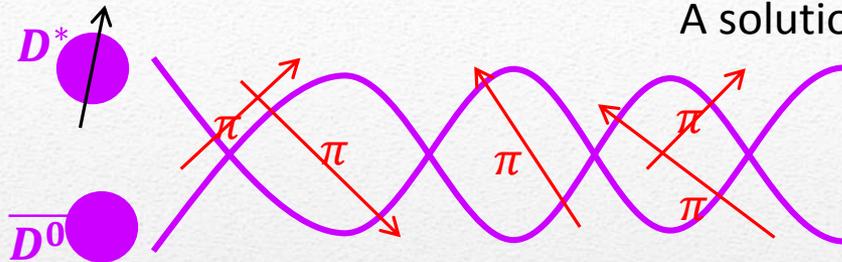

We tune our MC to reproduce CDF distribution of  $\frac{d\sigma}{d\Delta\phi} (p\bar{p} \rightarrow D^0 D^{*-})$

We get  $\sigma(p\bar{p} \rightarrow DD^* | k < k_{\text{max}}) \approx 0.1 \text{ nb}$  @  $\sqrt{s} = 1.96 \text{ TeV}$

Experimentally  $\sigma(p\bar{p} \rightarrow X(3872)) \approx 30 - 70 \text{ nb}!!!$

# Estimating $k_{max}$

A solution can be FSI (rescattering of  $DD^*$ ), which allow  $k_{max}$  to be as large as  $5m_\pi \sim 700$  MeV

$$\sigma(p\bar{p} \rightarrow DD^* | k < k_{max}) \approx 230 \text{ nb}$$

Artoisenet and Braaten, PRD81, 114018

However, the applicability of Watson theorem is challenged by the presence of pions that interfere with  $DD^*$  propagation

Bignamini, Grinstein, Piccinini, Polosa, Riquer, Sabelli, PLB684, 228-230

FSI saturate unitarity bound? Influence of pions small?

Artoisenet and Braaten, PRD83, 014019

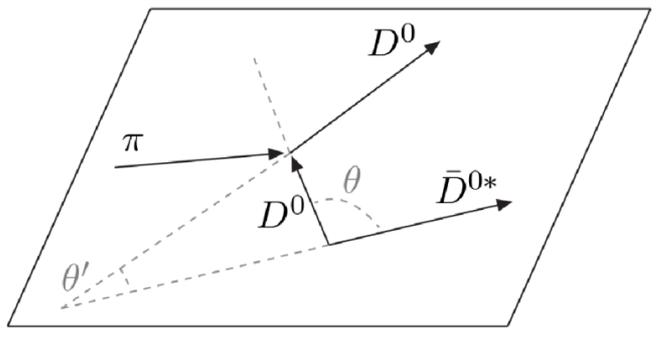

Guo, Meissner, Wang, Yang, JHEP 1405, 138; EPJC74 9, 3063; CTP 61 354  
use  $E_{max} = M_X + \Gamma_X$  for above-threshold unstable states

With different choices, 2 orders of magnitude uncertainty,  
limits on predictive power

# A new mechanism?

In a more **billiard-like** point of view, the comoving pions can **elastically interact** with  $D(D^*)$ , and **slow down** the pairs  $DD^*$

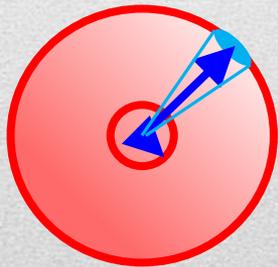

Esposito, Piccinini, AP, Polosa, JMP 4, 1569  
Guerrieri, Piccinini, AP, Polosa, PRD90, 034003

The mechanism also implies:  $D$  mesons actually **“pushed”** **inside** the potential well (the **classical 3-body problem!**)

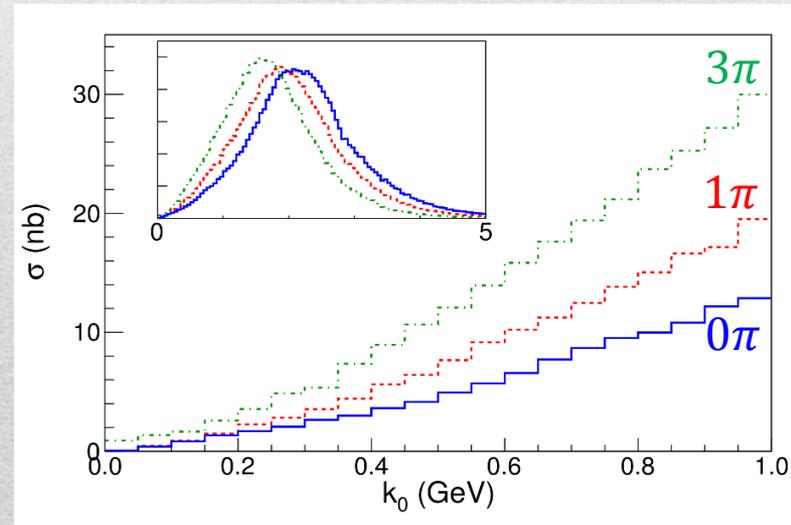

$X(3872)$  is a **real, negative energy bound state** (stable)

It also explains a small width  $\Gamma_X \sim \Gamma_{D^*} \sim 100$  keV

By comparing hadronization times of heavy and light mesons, we estimate up to  $\sim 3$  collisions can occur before the heavy pair to fly apart

We get  $\sigma(p\bar{p} \rightarrow X(3872)) \sim 5$  nb, **still not sufficient** to explain all the experimental cross section

# Hybridized tetraquarks – Selection rules

- Consider the **down quark part of the  $X(3872)$**  in the diquarkonium picture:  

$$\Psi_{\mathbf{d}} = X_{\mathbf{d}} = [cd]_0[\bar{c}\bar{d}]_1 + [cd]_1[\bar{c}\bar{d}]_0 \sim (D^{*-}D^+ - D^{*+}D^-) + i(\psi \times \rho^0 - \psi \times \omega^0)$$

↑  
Fierz rearrangement

- The closest threshold from below is  $\Psi_m \sim \bar{D}^0 D^{*0} \longrightarrow \Psi_{\mathbf{d}} \perp \Psi_m$  ✓

- But if we consider the **up quark part of the  $X(3872)$** :

$$\Psi_{\mathbf{d}} = X_{\mathbf{u}} = [cu]_0[\bar{c}\bar{u}]_1 + [cu]_1[\bar{c}\bar{u}]_0 \sim (\bar{D}^{*0}D^0 - D^{*0}\bar{D}^0) - i(\psi \times \rho^0 + \psi \times \omega^0)$$

- But then  $\longrightarrow \Psi_{\mathbf{d}} \not\perp \Psi_m$  ✗

- Only  $X_{\mathbf{d}}$  is produced via this mechanism  $\begin{cases} \longrightarrow \text{isospin violation} \\ \longrightarrow \text{no hyperfine neutral doublet} \end{cases}$

- $X_b$  (A) Diquark model predicts  $M(X_b) \simeq M(Z_b) \simeq (10607 \pm 2)$  MeV  
 (B) The closest orthogonal threshold is  $M(B^0 B^{*0}) = (10604.4 \pm 0.3)$  MeV  
 (C) This could either be **above threshold (very narrow state)** or **below (no state at all)**  
 (D) Experimentally the diquark model overpredicts the mass of the  $X$ :

$$M(Z_c) - M(X) \simeq 32 \text{ MeV}$$

- (E) We favor the below threshold scenario  $\longrightarrow$  no  $X_b$  should be seen

A. Esposito

# Production of hybridized tetraquarks

Going back to  $pp(\bar{p})$  collisions, we can imagine hadronization to produce a state

$$|\psi\rangle = \alpha|[qQ][\bar{q}\bar{Q}]\rangle_c + \beta|(\bar{q}q)(\bar{Q}Q)\rangle_o + \gamma|(\bar{q}Q)(\bar{Q}q)\rangle_o$$

If  $\beta, \gamma \gg \alpha$ , an initial tetraquark state is not likely to be produced  
The open channel mesons fly apart  
(see MC simulations)

If hybridization mechanism is at work, an open state can resonate in a closed one

$\alpha$  expected to be small in Large N limit, [Maiani, Polosa, Riquer JHEP 1606, 160](#)

**No prompt production without hybridization mechanism!**

Note that only the  $X(3872)$  has been observed promptly so far...

...and a narrow  $X(4140)$  not compatible with the LHCb one → **needs confirmation**

# Tetraquark
